but its chief use is to improve the texture of the soil, and render it better adapted to receive and retain moisture, so that a smaller portion of dung will have a greater effect than a larger would without it. No good agriculturist will trust to chalk alone on poor exhausted land, although he may do so where the soil is full of nutritive matter. In this last case however lime would be much more effectual; but chalk will make dung work well, and hence it is most frequently mixed into a compost with it, or alternate heaps of dung and chalk are put upon the land and mixed in the spreading. When chalk is used, it is of great importance to ascertain whether the natural soil contains more or less of calcareous matter. The less of this matter is found in it on analysis, the greater improvement is produced by chalk; hence the common saying, that "the farther you are from a chalk-pit, the more valuable is the chalk."

The soils most improved by it are the strong wet clays, which contain a portion of iron. Chalk acts as an absorbent, corrects astringency, and prevents, by its interposition between the particles of clay, that running into a solid mass, which is so detrimental to the roots of plants by entirely excluding atmospheric air. On loose sands its effect is different; there it acts chiefly as a cement, and the more argillaceous it is, the better it binds the siliceous particles. For light soils marl is preferable, especially when a considerable coat can be put on the land. The clay which is so abundantly used in some parts of Norfolk, and is found in many places at a small depth below the surface, owes much of its virtue to the calcareous matter which it contains, and where this is deficient, it will not much improve the soil until chalk or lime be added. Chalk is used wherever it can be procured within a moderate distance, and the soil is stiff; as in the counties of Essex, Suffolk, Berkshire, Middlesex, Buckinghamshire, and many others. In those districts where chalk is much used, it is generally put on the land in autumn, and not ploughed in till it has been exposed to the frost; or it is laid in long heaps on a headland, or by the side of a road or lane, and there turned over and mixed with the earth on which the heaps are laid. If it be exposed to the sun in summer, it must be carefully covered with earth, or it will harden so much by drying that it will be very difficult to pulverise it afterwards, and the frost will not have the same effect upon it. Ten tumbril loads of chalk, and as many of good farm-yard dung, are a very good dressing either on a fallow for wheat or previous to sowing turnips. When chalk is laid on permanent meadows, it promotes the growth of white clover; but except the meadows are wet and produce rushes, it is of no very great benefit to the grass, although it shows its effect when the grass is broken up. When land is cultivated according to the convertible system, the best time to put chalk on the land is when it is about to be ploughed up. If the grass is fed off the last year, the chalk may be put on during the preceding winter, and simply spread over the grass; it will thus be pulverised by the frost, will sweeten the pasture, and its full effect will be perceived in the first grain-crop after the land is ploughed up. When chalk has been some time on the land, it is gradually carried below the soil by the filtration of the surface-water, and by the action of earthworms, which are continually carrying upwards and depositing on the surface the fine earth removed from below the chalk dressing. After a few years therefore it requires to be renewed, which shows the advantage of putting on a moderate quantity and repeating it in six or seven years, in preference to putting on a large quantity at once, unless where lands are reclaimed from a state of waste, and require to be improved by a large admixture of calcareous matter before they can be made productive by enriching manures. This is the case with those yellow loams which contain much iron, and which are generally found under the *iron pan*, so well-known to all those who improve poor light heath-land. [**BARREN LAND.**] The quality and effects of chalk as a dressing depend, not only on the deficiencies of the soil to which it may be applied, but also on its own varying composition, and that chalk is best, which is found to contain the largest per centage of phosphate of lime in addition to the calcareous and clayey parts of which it mainly consists.

An important use of chalk is to form ponds in porous soils for the use of cattle. A stratum of chalk a few inches thick, protected by a coat of gravel and sand to prevent its being trod through, will effectually retain the water; and if a considerable proportion of salt is beat up with it and intimately mixed, it will effectually prevent worms from making lodgments in it, and keep in water for a very long time. It is of advantage to throw chalk into all ponds used by cattle; it corrects any acidity which may arise from stagnation, and the water in which chalk is diffused, is more wholesome than that which contains clay alone. In fattening calves chalk is of the greatest use; it may be laid in the calf-pens for them to lick, which they will readily do, or it may be scraped and mixed with a small quantity of salt, and laid in a small manger within the reach of each calf. It effectually prevents scouring, and keeps their digestion in a proper state.

In many parts of England the whole sub-soil to a great depth is a solid mass of chalk, and the earth which covers it contains very little else than carbonate of lime, with a small portion of vegetable matter in a decomposed state. In this soil a short sweet herbage grows, which is extremely grateful to sheep; according to the chalky hills, called downs, in Sussex, Wiltshire, &c., are chiefly devoted to sheep-pasture. Along the sides of these hills, where the waters continually accumulate the finer particles of the soil which are washed down from above,

some very productive arable lands are formed, and very good crops of barley are raised. There is a plant which seems to delight in chalky soils, and to flourish better there than in deeper and richer earth. This is the saintfoin (*Hedysarum Onobrichis*), and its introduction among the cultivated grasses has greatly raised the value of chalky land, previously considered too poor to repay cultivation. It not only produces an excellent fodder, superior to meadow-hay and scarcely inferior to clover; but by its roots it so divides and enriches the soil, that after having covered it with luxuriant crops of hay for several years, it leaves it in a fit state to produce excellent crops of grain, with very moderate manuring.

Chalky soils are not subject to the same perennial weeds which infest richer lands; couch-grass is seldom found in chalk, but the annuals, such as May-weed, charlock, poppy, crow-foot, and several others, abound in it. When a chalky soil produces thistles, it is an indication of its containing a portion of argillaceous earth, which improves its fertility.

CHALK FORMATION, in NAT. HIST. DIV.

CHALLENGE. [JURY.]

CHALYBEATE SPRINGS. Of all mineral waters those containing iron are the most common; but such only are considered chalybeates, in a medical sense, in which the iron predominates, if not in quantity, at least in action, over the other ingredients. The quantity and combinations of the iron vary in every spring; but it is generally combined with carbonic acid, in the form of protoxide or protocarbonate, and is deposited in considerable quantity in the form of oxide, when the water reaches the external air. The presence of chalybeate springs may generally be detected by the appearance of the stream or water-course. The inky or styptic taste of the water also indicates the presence of iron. In other instances it is combined with sulphuric acid, in the form of sulphate of iron; it is often associated with alumina; and more rarely hydrochloric acid is combined with it. When a large proportion of free carbonic acid is present, such springs are termed *acidulo-chalybeate*.

The temperature rarely exceeds that of the ordinary temperature of spring water, and it is generally lower. Of the former class several exist on the Continent; Bath is the only example in Britain. Cold chalybeate waters, with proper conveniences for their employment, are not very numerous in Britain. Tunbridge, Harrowgate, and Holywell, in England and Wales; and Peterhead, Dunblane, and Bonnington near Edinburgh, in Scotland, are the chief. Chalybeate waters may be employed either internally or externally in the form of baths; the former mode is the most common in this country. The use of chalybeate waters possesses many advantages over the other modes of administering iron, and not only enables many to employ this metal, but likewise to persevere with it for a much longer time. This is more particularly the case when much free carbonic acid exists in the water, as in the *acidulo-chalybeate* springs. The cold temperature of the water certainly disagrees with many persons, but this may be obviated, either by beginning with the Bath waters, or pouring the quantity intended to be used into a little warm water, or adding a tea-spoonful of the compound tincture of cardamoms to the first glass. The persons who require chalybeate waters are those who need tonics to improve their constitution and remove a tendency to disease; or convalescents from acute disease; or persons who have been debilitated either by a residence in warm climates or by severe mental exertions. Persons of a plethoric habit can rarely use them without undergoing some preparatory treatment. Like iron, they are improper during pregnancy, or the course of an inflammatory disease, or the existence of organic affections of the heart or liver, or tendency to apoplexy. When alone, or still more when combined with alumina, they often cause constipation, which requires to be obviated: in some individuals, especially at the commencement of their use, an opposite state occurs: in either case a black colour of the motions is observed, which should excite no alarm, as it simply arises from the tannin of the food uniting with the iron, and forming a black tannate of iron. During the use of chalybeate waters, the diet of the patient requires careful regulation.

The acidulous and carbonated chalybeate waters do not bear transportation well; the waters which contain sulphate of iron may be sent to a distance with less injury to their qualities. Two methods have been proposed to prevent the deterioration of the acidulous and chalybeate waters during removal to a distance; the one by boiling the corks previous to putting them into the bottles; the other by merely driving an iron nail through the cork, so as to be in contact with the water, which latter method is even said to increase the quantity of iron held in solution by the water.

Baths of chalybeate water are sometimes used along with the internal employment of the waters, sometimes alone. They afford great assistance in the cure of diseases for which iron is proper, and can sometimes be employed when the internal use of iron is impracticable. Those of this country are less resorted to than Alexisbad in the Harz, or those of Nassau. [IRON; BATHING.] Gairdner 'On Mineral and Thermal Springs.'

CHAMÆLEON, a constellation near the South Pole, formed by Bayer. It contains no stars of conspicuous magnitude.

CHAMBER, a recess formed at the lower extremity of the bore of a gun, howitzer, or mortar, and in the direction of the axis, in order to receive the charge of powder by which the shot or shell is to be pro-

jected. Chambers are made of various forms, the Gomer, the pear-shaped, the cylindrical, the hemispherical, and the Paixhan; the magnitude of the chamber is such as to allow it to contain the quantity of powder constituting the charge, but its diameter is less than that of the bore. It is used in guns in which the charge of powder being small in comparison to the size of the bore, great loss of power would ensue from the explosion of the powder, in the empty space below the shot and breach, unless the bore were contracted to be nearly filled with the powder.

The Gomer chamber, so called from the name of the inventor, is made in the form of a frustum of a cone, terminating with a concave hemisphere at the smaller parts, which is the extremity of the chamber, and the greater circumference coinciding with that of the bore. The shot or shell, being placed in close contact with the conical part of a chamber of this kind, thus becomes subject to the whole force of the elastic fluid.

The Gomer chamber is the best when the charges are large, and the cylindrical when they are very small.

CHAMBERLAIN (*custos cubiculi*, or *cubicularius*, keeper of the chamber). Cubicularius was the Roman name for a slave whose special business was to look after the rooms or chambers in the house, introduce visitors, and the like. The cubicularius was thus a confidential slave or freedman, as the case might be, and a kind of guardian of his master's person. Under the emperors the cubicularii were officers in the imperial household; and were called the "cubicularii sacri cubiculi," the chamberlains of the imperial chamber. ('Cod.' xii. tit. 5.) The emperor's wife, the Augusta, also had her chamberlains. This office, like many others in royal households, is derived from the usages of the later Roman Empire. In the Anglo-Saxon times, in England, the chamberlain appears to have had the name of Camerarius, and had the keeping of the king's treasure (Ealred, in 'Vit. S. Edw. Confess.' c. ii. p. 9), by which name this officer also occurs in the Domesday Survey. The word chamber (French, *chambre*) is from the Latin camera.

The office of lord great chamberlain of England was once of the highest dignity, and was held in grand serjeanty from the second year of King Henry I. by the family of De Vere, from whom it passed, by a female heir, to the family of Bertie. By the statute of precedence, 31 Hen. VIII., the great chamberlain's place was next to that of the lord privy seal. In 1714 the Marquis of Lindsay, then hereditary great chamberlain of England, having been raised to the dukedom of Ancaster, surrendered this precedence for himself and his heirs, except only when he or they should be in the actual execution of the duties of the said office, in attending the person of the king or queen, or introducing a peer into the House of Lords. This surrender was confirmed by 1 Geo. I. c. 3. The duties which now devolve upon the great chamberlain are, the dressing and attending on the king at his coronation; the care of the Palace of Westminster; the provision of furniture for the Houses of Parliament, and for Westminster Hall, when used on great occasions; and attendance upon peers at their creation, and upon bishops when they perform their homage. On the death of Robert, the last duke of Ancaster but one, in 1779, the office of hereditary great chamberlain descended to his two sisters, Priscilla, Lady Willoughby de Eresby, and Georgiana Charlotte, Marchioness Cholmondeley. The office is now jointly held by the families of Cholmondeley and Willoughby de Eresby, and the honours are enjoyed in each alternate reign by each family successively.

The office of lord chamberlain of the king's household is changed with the administration. He has the control of all parts of the household (except the ladies of the queen's bed-chamber) which are not under the direction of the lord steward, the groom of the stole, or the master of the horse; the king's chaplains, physicians, surgeons, &c., as well as the royal tradesmen, are by his appointment; the companies of actors at the royal theatres, as part of the household, are under his regulation, and he is also the licenser of plays. [CENSORSHIP OF THE PRESS.] One of the officers in his department is styled Examiner of Plays.

The chamberlain of the corporation of the city of London is an officer elected by the freemen who are liverymen. By an act of common council of 5 Henry IV. the office is an annual one, but it is very rarely that the existing officer is not re-elected. There has been no such opposition since 1778. The duties of the chamberlain are judicial and administrative. He admits on oath all persons entitled to the freedom of the city, and hears and determines all matters of complaint between masters and apprentices, and may commit either. He may discharge the apprentice from his indentures, and a part of the premium may be recovered by a peculiar process in the Lord Mayor's court. An appeal is said to lie from the decision of the chamberlain to the lord mayor. The chamberlain has the conservation of lands, moneys, or goods of citizens who die intestate, leaving orphans, on the application of such orphans or others on their behalf, for which purpose the chamberlain is deemed in law a corporation sole; but such applications are now rarely made. As treasurer of the corporation, he has to receive all rents, profits, and revenues of markets and other items of receipt forming the income of the corporation, and to pay all money on account of the corporation upon competent warrants or orders. The fixed annual income of the chamberlain is 1160*l.* 9*s.* 4*d.*:

his "ancient bill of fees" is 94*l.* 4*s.* a-year. He obtains an annual profit of from 1000*l.* to 2000*l.* from balances of the corporation money retained in his hands. This principle of remunerating a public officer having been objected to by the Commissioners of Corporation Inquiry ('Second Report,' p. 102), a new system is about (1859) to be introduced.

In the Exchequer Court of the County Palatine of Chester there is a chamberlain, an office generally held by some nobleman; and there is also a vice-chamberlain.

There was an officer called the chamberlain in two hundred and three of the municipal corporations investigated in 1834 by the Commissioners of Corporation Inquiry.

CHAMELION MINERAL. [MANGANESE—*Manganic Acid.*]

CHAMPAGNE WINE. [WINE.]

CHANCE. This word has been used in two senses, as opposed to Providence, and as opposed to certainty. For the theory of chances, in the latter sense, see PROBABILITIES, THEORY OF.

CHANCE-MEDLEY, in English law, is a singular corruption of *chaudemellé*, a term well known in old French legal phraseology, and in the barbarous Latin of ancient ordinances translated *calida melleia*. The term in French law denoted, consistently with its etymology, a casual affray or broil, accompanied with heat or violence, but without deliberation or preconceived malice. (Ducange, 'Gloss.' Meslie.) In English law, it can hardly be doubted that chance-medley originally meant the same thing; but in modern times the expression is limited to a particular kind of homicide, namely, the killing another in self-defence upon a sudden and unpremeditated encounter. There is often much difficulty in distinguishing homicide by chance-medley, which, though an offence by law, is excusable on the ground of self-defence, from the crime of manslaughter. The general distinction is, that if both parties are actually fighting, he who gives the mortal stroke is guilty of manslaughter; but if one of them at first refuses to fight, and on being closely pressed, retreats as far as he can, and at last, in order to avoid his own destruction, kills his antagonist, this is homicide excusable on the ground of self-defence; or, as it is inaccurately called, chance-medley. (Foster's *Crown Law*, tit. 'Homicide'.)

CHANCEL, that part of a church east of, or beyond, the nave, in which the communion table or altar is placed, with the area before it, in which the congregation assemble when the Eucharist is administered. This part of a church was often separated from the nave or body of the church by lattice work, *cancelli*, and it was from this circumstance that the term chancel seems to have originated. The use of the term is restricted to parish churches and churches which have no great choir, and no aisle or chapels around the choir or chancel. The great arch dividing the chancel from the nave in Gothic churches is called the chancel arch—and is regarded by ecclesiological writers as symbolising the gate of heaven.

In some churches we may hear of the chancel of a particular family. This is in cases in which some particular family has had a private oratory within the church, which has usually been also the burial place of the family. These private chapels or chantries are sometimes called chancels, for the same reason that the great choir is sometimes so called; that is, in consequence of being divided from the rest of the church by *cancelli*.

CHANCELLOR (in Latin, *Cancellarius*). The primary meaning of cancellarius is "qui ad cancellos assistit," one who is stationed at the lattice-work of a window or a doorway, to introduce visitors, &c. A cancellarius in this sense was no more than a door-keeper. The emperor Carinus made one of his cancellarii prefect of the city, a promotion which caused great dissatisfaction. (Vopiscus, 'Carinus'.) In another sense, cancellarius was a kind of legal scribe, so called also from his position at the cancelli of the courts of law. The cancellarius, under the later emperors, and in the Constantinopolitan court, was a chief scribe or secretary (*ὁ μέγας λογοθέτης*), who was ultimately invested with judicial powers, and a general superintendency over the rest of the officers of the emperor. He was called cancellarius because he sat *intra cancellos* (within the lattice), a screen dividing off a portion of a larger room for the sake of greater privacy; from which circumstance the chancel of a church also acquires its name.

The prelates of the Roman church had likewise an officer so called; in the Church of England, each bishop has a chancellor, to whom are entrusted judicial functions. All the modern nations of Europe had a chancellor, though his powers and duties seem to have varied in each.

In England the chancellor was originally the king's chief secretary, to whom petitions were referred, by whom patents and grants from the crown were approved and completed, and by whom reports upon such matters were, if necessary, made to the king; hence he was sometimes styled Referendarius. This term occurs in a charter of Ethelbert, A.D. 605; and Selden considers it synonymous with chancellor, a name which, he says, first occurs, in the history of England, in the time of Edward the Elder, about 920.

In the capacity of secretary he was the adviser of his master; prepared and made out his mandates, grants, and charters, and finally (when seals came into use) affixed his seal. Hence, or perhaps because in early times he was usually an ecclesiastic, he became keeper of the king's conscience, examiner of his patents, the officer by whom prerogative writs were prepared, and keeper of the great seal. The

last ecclesiastic who exercised the office was John Williams, archbishop of York, who was lord keeper from July 10, 1621, to November 1, 1625; his friend and secretary, John Hacket, who became bishop of Lichfield and Coventry, wrote his life in a volume of singular interest, which he entitled '*Scrinia Reserata*.'

In early times, and before the precise limits and extent of the jurisdiction of the different courts of justice were clearly defined, the special interference of the crown, as the fountain of justice, was frequently sought against the decisions of the courts of law; as well as in matters which were not cognisable in the ordinary courts, or in which, from the maintenance or protection afforded to his adversary, the petitioner was unable to obtain redress. The jurisdiction with which the modern chancellor is invested, thus had its origin in that discretionary power, that ultimate jurisdiction to administer justice, which remained in the crown on the establishment of courts of justice with properly defined authority; therefore, although the exercise of those powers in modern times is scarcely, if at all, less circumscribed and hemmed in by rule and precedent than the strict jurisdiction of the courts of law, controversies have occasionally arisen as to the powers of the chancellor, the most celebrated being that between Sir Edmund Coke and Lord Chancellor Ellesmere.

The style of this officer in England is, since the union with Scotland, Lord High Chancellor of Great Britain. He takes rank above all dukes not of the blood royal, and next to the archbishop of Canterbury. He is appointed by the delivery of the great seal into his custody, and the resumption of the great seal by the sovereign determines his office. By virtue of his office he is the principal adviser of the crown in matters of law, and a privy counsellor, speaker and prolocutor of the House of Lords, chief judge in the court of chancery, and the head of the profession of the law; visitor in right of the crown of all hospitals and colleges of royal foundation; and patron of all crown livings under the value of 20*l.* a year, according to the valuation made in the reign of Henry VIII., and confirmed in that of Elizabeth. He appoints nearly all the judges of the superior courts (the prime minister of the day nominating the two chief justices), the commissioners in bankruptcy, and the judges of the county courts. He also appoints and removes all justices of the peace, though usually only at the recommendation of lords-lieutenant of counties. He issues writs for summoning parliaments, and transacts all business connected with the custody and use of the great seal. He is a conservator of the peace, and may award precepts and take recognisances to keep the peace; and has concurrent jurisdiction with the other judges of the superior courts, with respect to writs of habeas corpus. Except in the case of service of process, given to him by some recent statutes, the lord chancellor has no jurisdiction in Scotland.

The authority of lord chancellor and lord keeper are made the same by the Stat. 5 Eliz. c. 18, though it is not now customary to appoint a lord keeper. The last lord keeper was Lord Henley, in 1757. The great seal is, however, sometimes put into commission during the temporary vacancy of the office or the sickness of the chancellor, the seal being entrusted to the chief commissioner.

The chancellor is not only a judicial officer of the crown, but he has important political functions; he has a seat in the cabinet, and usually takes an active part in public measures. He resigns office with the party to which he is attached. The inconvenience and necessary delay arising from his removal during the pendency of suits in his own court and before the House of Lords, and the arrear of business caused by the variety of duties which he is called upon to perform, have suggested the necessity of some alteration in the constitution of the office. Many expedients have been tried: vice-chancellors have been appointed; the master of the rolls has been empowered to assist in the usual and ordinary functions of the court of chancery; a court of appeal in chancery has been constituted; and a number of useful and important reforms have been made in the subordinate offices of the court. But such is the pressure of business on this great officer, that all these means have been ineffectual to remedy the inconvenience of so many important duties being devolved on one individual. Various propositions for the creation of a ministry of justice have been made; and it is not improbable that, before long, material alterations in the nature and duties of this great office will be effected.

By the Stat. 3 & 4 Will. IV. c. 111, in consideration that the chancellor had lost the patronage of certain offices then abolished, the crown is empowered to grant an annuity of 5000*l.* a year to the lord chancellor or lord keeper on his resignation of office. There is also a lord high chancellor of Ireland, whose authority within his own jurisdiction is in most respects the same as that of the lord high chancellor of Great Britain. (Selden, 'Off. Ch.'; Blackst. 'Comm.'; Story 'on Equity Jurisprudence'.)

The *Chancellor of a Church or of a Bishop* is vicar-general to the bishop, holds his courts, and directs and assists him in matters of ecclesiastical law. He has a freehold in his office, and he is not necessarily an ecclesiastic; but if he is a layman, or married, he must be a doctor of the civil law. (Blackst. 'Comm.' 37 H. VIII. c. 17.)

The *Chancellor of a Cathedral* is an officer who superintends the regularity of the religious services.

The *Chancellor of the Duchy of Lancaster* presides either in person or by deputy in the court of the duchy of Lancaster, concerning all matters of equity relating to lands holden of the king, in right of the

duchy of Lancaster. The court is held four times a year by the Vice-Chancellor at Liverpool.

The *Chancellors of the Universities of Oxford and Cambridge* are elected by the respective corporate bodies of which they are the heads; they exercise exclusive jurisdiction in all civil actions and suits where a member of the university or privileged person is one of the parties, except in cases where the right to freehold is concerned. In both the English universities the duties of the chancellor are in nearly all cases discharged by a vice-chancellor.

The *Chancellor of the Exchequer* is under-treasurer, and holds the seal of the exchequer. The office of lord high treasurer is now executed by the lords commissioners of the treasury. The chancellor of the exchequer is the principal finance minister of the crown, and the office is generally held by the prime minister when he is a member of the House of Commons. The legal functions of the chancellor of the exchequer are now merely formal. Bills in the exchequer are addressed to him and to the barons of that court, and on some occasions (as on his appointment) he sits in court; but all the legal business is transacted by the barons. If the chief baron and barons are equally divided in opinion, the chancellor of the exchequer may be required to rehear the cause with the barons, and give his decision. The last instance occurred in 1735, when Sir Robert Walpole gave his decision upon a question of considerable doubt and difficulty which is said to have given great satisfaction. (Fowler's 'Exchequer Practice'.)

The *Chancellor of the Order of the Garter*, and other orders of knighthood, seals and authenticates the formal instruments of the chapter, and keeps the register of the order. He exercises various functions at the installation of the knights, and during their meetings and processions.

CHANCELLOR OF SCOTLAND. As in England, the chancellor of Scotland was always a high officer of the crown, and had great influence with the king and authority in his councils. As in England too, that authority at length extended itself beyond its former limits, and affected the whole judicial power of the kingdom. Its operation and effect in the two countries, however, was different: for while in England the chancellor only carved out for himself a jurisdiction in equity, in Scotland he reached the head of the administration of justice, and sat in a court which dispensed both equity and common law, and the course of proceeding in which all the other judicatures of the realm were bound to follow.

In 1425, shortly after the return of James I. from his long captivity in England, the "chancellor and with him certain discrete persones of the thre estates chosen and depute by the king" were erected into the court of the session, for the final determination of all matters competent to the king and his council. This court however expired with Bishop Wardlaw, from whom in all likelihood it originated; and the former policy of determining suits by the old common law was restored. This continued (with the exception of an attempt to the contrary in 1457, probably under the influence of Bishop Shorsewood, the favourite and confessor of King James II.) till the time of Bishop Elphinstone, to whom undoubtedly may be ascribed the crafty acts passed in 1487 for the recovery of the large jurisdiction of the chancellor and court of the session, as well as the act 1494, c. 5, to enforce in the courts the study and practice of the canon and civil laws. Nor perhaps shall we greatly err in conceiving his zeal to have been employed in establishing in 1503 the court of daily council, which was essentially a restoration of the old court of the session. But all these proved only preparatory steps to the erection of the court of council and session, or college of justice, which was instituted in 1532, and has continued to our own time. Of this college the chancellor, or, as he then began to be styled, lord chancellor of Scotland, was to be principal; and as on the one hand it was the supreme court of the kingdom, and on the other all inferior courts were required to copy its proceedings, it wielded the whole judicative power of the country. It early claimed also, and exercised, a large legislative power under the statutes permitting it to pass acts of sederunt; and the officers who executed its warrants and decrees, were either its own macers or else messengers, over whom it obtained complete control. These powers the court wielded so as to effect nearly an entire change of the law. The ecclesiastical estate for some time predominated both on the bench and at the bar. The consequence was, the canon and civil laws became, what indeed they used to be styled, the common law of the land, and the old common law became antiquated, and ultimately obsolete. The new system was too effectually established to be much disturbed by the Reformation; and the union with England, where the old common law had been and has ever continued the antagonist of Roman jurisprudence, has accordingly not produced any assimilation of the laws of the two countries. At the Reformation the authority, though not the spirit, of the canon law may be considered, in matters ecclesiastical at least, to have ceased; and not long afterwards ministers of the Gospel were disabled by statute from being either of the bench or bar. Since the union, when both portions of the island became one great mercantile community, various provisions have been made to improve and assimilate the laws of the two kingdoms; but these have been confined to that one branch of jurisprudence, and an apparently invincible repugnance has been evinced to more extensive changes.

The procedure in the court of session in Scotland resembles in some

points that of the court of chancery in England. Both courts indeed, and the ecclesiastical courts of both countries, borrowed their forms from the court of Rome, and with these last the forms of the court of session in many respects still agree. The bill or written supplication to the court for letters, whether of summons or of diligence, is of the same nature with the supplication for letters in the court of Rome: and it is observable that when the desire of the bill is granted, it is in the same terms in both courts. The condescendence and answers are plainly derived from the articuli and responsiones of the papal tribunal. The initialia testimonii, or purging of a witness, are identical with the interrogatoria generalia of that court. Letters of advocacy, suspension, and reduction, are well known there. The "malè appellatum et benè processum" is but verbally translated in the phrase of the Scots court, "Finds the letters orderly proceeded;" and letters of horning, caption, and relaxation, bear their papal origin impressed upon them. It appears also that from an early period the court issued commissions to its macers to perform judicial duties, as the ecclesiastics appoint the inferior church officers their legates and commissaries for the like purposes; and at an early time also the judges began the yet subsisting custom of changing their name on their elevation to the bench, in imitation, as it seems, of the like custom on elevation in the papal hierarchy.

From what is above stated, we may see why there is no court of chancery in Scotland, separate from the courts of common law, as in England; the whole judicatures of Scotland having become subject to the court of session, where the chancellor presided, dispensing what has been described as both equity and common law. But from the earliest times there has been a chancery in Scotland, and many of the early chancellors are described as "clerici cancellarii."

A list of the chancellors as of the other great officers of the crown in early times, is given in Crawford's 'Officers of State.' A subsequent list is given by Chalmers in his 'Caledonia;' but a correct or complete list has not yet, it is believed, been compiled; and except to the Scottish antiquary the matter is not one of any great interest. The earliest chancellor whose existence can be authenticated, was Constantine, earl of Fife, chancellor, temp. Alex. I. Alan St. Edmonds, bishop of Caithness in 1291, seems to be the only chancellor nominated by King Edward I. of England, who associated in office with him Walter de Agmodescham (Ayloff's 'Cal.' 105), and thereafter Adam de Bodingdon, who was vice-chancellor, 1291 (with half a mark a day for his salary, Rotul. 'Scot.' 9), and chancellor in December of the same year, the bishop of Caithness having previously died. He was followed by nearly thirty ecclesiastical chancellors, till, in 1460, Andrew, Lord Avendale, held the office. After three episcopal chancellorships, Colin, earl of Argyll, held office in 1483 to 1488; and after him came Archibald, earl of Angus, and George, earl of Huntley. James Beaton, abbot of Dunfermline, became chancellor in 1513. In 1525, on the removal of the duke of Albany from the regency, the earl of Angus turned Beaton, now bishop of St. Andrews, out of the chancellorship, which with several other offices he then engrossed to himself. On Angus's fall the place was given, in 1528, to Gavin Dunbar, archbishop of Glasgow, in whose time the college of justice was instituted.

The series of chancellors need not be further continued. By the treaty of Union it was provided that there should in future be but one great seal for the United Kingdom, and that a seal should be kept and used in Scotland for such private rights or grants as had usually passed the great seal of Scotland. The office of chancellor of Scotland then properly expired, and none have been appointed to it since the earl of Seafeld, who was chancellor at the time of the Union.

CHANCERY (*Cancellaria*); the term is derived from Chancellor, *Cancellarius*, and signifies the court where that judge exercises his functions. There are several chanceries, as there are several chancellors; but the place where the Lord High Chancellor's judicial functions are exercised is especially called the Chancery.

The principal part of the business of the Court of Chancery consists in the administration of *equity*, a name which in this country comprehends a particular set of rules, having the force of law, which are applicable to such matters as belong to the jurisdiction of the court. [EQUITY.] The court of chancery of the County Palatine of Lancaster, the court of the Stannaries, the Lord Mayor's court of London, and various local courts have a similar jurisdiction.

The Lord Chancellor, the Lords Justices of the Court of Appeal in Chancery, the Vice-chancellors, and the Master of the Rolls are the judges by whom equity is administered in Chancery. Each of these judges has a separate court. These courts have no fixed or permanent situation; but except on the first day of term, when they meet at Westminster, the former are held in Lincoln's Inn, and the last at the Rolls, in Chancery-lane.

The Court of Chancery is a name which properly belongs to the Lord Chancellor's court, and the court of the Lords Justices and Vice-Chancellors. The Master of the Rolls, who is appointed by the crown by letters patent, and holds his office for life, administers equity in a separate court, called the Rolls. He has the power of hearing and determining originally the same matters as the lord chancellor, excepting cases in lunacy, which are specially delegated by the crown to the chancellor and lords justices. All orders and decrees pronounced by the Master of the Rolls must be signed by the Lord Chancellor before they are enrolled. This officer has precedence next to the lord

chief justice of the Queen's Bench. The office is one of high antiquity, and the salary is 6000*l.* a year. The Master of the Rolls has very considerable patronage, connected principally with the public records, of which he is the keeper.

The Court of Appeal in Chancery was created by the statute 14 & 15 Vict. c. 83, to exercise primarily the same appellate jurisdiction as the lord high chancellor, that is to say, to hear and determine appeals from the decrees of the vice-chancellors and master of the rolls. The two judges (who are called lords justices, and have precedence after the master of the rolls) sitting together, or with the chancellor, constitute this court of appeal; but, like the lord chancellor, they may take and dispose of original causes. The lords justices receive from the crown the same authority on matters of lunacy as the chancellor, and they, sitting together without the chancellor, constitute the Court of Appeal in bankruptcy.

The office of Vice-Chancellor was first created by stat. 53 Geo. III.,

24. There are now three vice-chancellors who, according to the dates of their appointment, take precedence next to the lords justices, they are appointed by the crown by letters patent, and hold their office during good behaviour. They have power to hear and determine all matters depending in the Court of Chancery either as a court of law or as a court of equity, or as incident to any ministerial office of the said court, or which are subjected to the jurisdiction of such court or of the lord chancellor by any special act of Parliament, as the lord chancellor shall from time to time direct. But all orders and decrees of the vice-chancellors must be signed by the lord chancellor, and the vice-chancellor has no power to alter or discharge any decree or order made by the lord chancellor, unless authorised by the lord chancellor, nor any power to alter or discharge any order or decree of the master of the rolls. The salary is 5000*l.* a year.

Each of these judges, or courts, has nearly an equal share of *original* power to dispense equity. An appeal (which, strictly speaking, is nothing more than a rehearing of the cause) may be had, as we have seen, from any decision of the master of the rolls or vice-chancellors to the lord chancellor, or to the Court of Appeal in Chancery, which has been of late years principally occupied with such appeals, original causes being generally confined to the courts of the master of the rolls and the vice-chancellors.

Besides the judges just mentioned, there were formerly other officers of the Court of Chancery by whom certain parts of its equitable jurisdiction were exercised. The principal of these officers were the masters in ordinary, and the accountant-general. The former office has been abolished; the latter remains one of the most important officers of this court. [ACCOUNTANT-GENERAL.] The masters were ten in number, besides the master of the rolls, who was the chief of them. It was their duty to execute the orders of the court upon references made to them, and by reports in writing to show how they had executed such orders; but it would be impossible to specify every head of reference to the masters, because they were almost as numerous as the subjects of the court's jurisdiction. Their duties have now been transferred partly to the judge and partly to the chief clerks of the judge. The latter have now to take the accounts of executors, administrators, or trustees, or between any parties whatsoever; to inquire into, and decide upon, the claims of creditors, legatees, and next of kin; to sell estates, and to approve of the investment of trust-money in the purchase of estates, and, for this purpose (or for any other, as the case may be), to investigate titles, and settle conveyances, referring the same, when necessary, to one of the six conveyancers appointed to advise the court in such matters; to inquire and report on applications for the appointment of guardians for infants, and the sums to be allowed for their maintenance and education; to settle lists of contributions on the winding up of joint-stock companies; and generally to inquire into and inform the conscience of the equity judge upon such matters of fact as are referred to them.

Besides these officers, each court has its registrars, and the Court of Chancery generally a body of taxing masters, to tax the bills of costs of the suitors, and a numerous staff of record and writ clerks, who attend to its process, and file and preserve its proceedings.

The jurisdiction exercised in the Court of Chancery will be explained under another head [EQUITY]; in this place it will be sufficient to refer to another and distinct though but a small part of its business, which arises on what is called *the common law jurisdiction of the Court of Chancery*.

It is here that proceedings by and against the crown (other than matters of revenue, which are cognisable in the Exchequer) originate. [MONSTRANS DE DROIT; PETITION OF RIGHT.] To this common law jurisdiction of the Court of Chancery also belongs the power of issuing certain writs; particularly the commissions of the peace, and the writs of *habeas corpus*, and of *certiorari* and *prohibition*. "In this ordinary or legal court," says Blackstone, "is kept the *officina justitiæ*, out of which all original writs that pass the great seal, all letters patent, and all commissions of charitable uses, sewers, idiocy, lunacy, and the like do issue." The issuing of original writs however is now unfrequent; for these writs, which were formerly the foundation of all actions in the courts of law at Westminster, have, with few exceptions, been abolished by recent statutes.

The place where this common law jurisdiction is exercised is the

petty-bag office, which is kept solely for this purpose; and the Court of Chancery, in respect of this jurisdiction, is said to be a court of *record*, which, as a court of equity, it is not.

In each of the counties palatine of Lancaster and Durham, and in Ireland, there is a Court of Chancery, which dispenses the same equity within the limits of its jurisdiction as the High Court of Chancery. In the Irish Court of Chancery the lord chancellor of Ireland presides. From the Lancaster court the appeal is to the lords justices; from the lord chancellor's decree, or that of the Court of Appeal in Chancery, the appeal is immediately to the House of Lords.

In imitation of the High Court of Chancery in England, various local courts of equity have sprung up in the British dominions and dependencies, which are generally called courts of chancery; but the equity administered in them appears not to be the settled system which exists in this country, the governors of the colonies being generally the judges.

Many of the states of North America have their courts of chancery; but the equitable jurisdiction of some of these is, it seems, more discretionary than that of our own courts of equity. In others of the states the courts of equity which formerly existed have been abolished; and in New York especially, the system of equity which was formerly separately administered as in England, has now been consolidated with the law, so as to constitute one system of jurisprudence, administered in one series of tribunals of original and appellate jurisdiction.

CHANCERY, INNS OF. [INNS OF COURT.]

CHANTRY (in the middle-age Latin, *Cantaria*), a private religious foundation, of which there were many in England before the Reformation, established for keeping up a perpetual succession of prayers for the prosperity of the founder's family while living, and the repose of the souls of those members of it who were deceased. These foundations owed their origin to the opinion prevalent in the early Church, of the efficacy of prayer in respect of the dead as well as the living; and amongst the English, always a devout people, it prevailed in all ranks of society. The inscriptions upon the gravestones of persons of ordinary condition in the times before the Reformation almost always began with "Orate pro animâ," which was an appeal to those who resorted to the church, to remember to pray for the soul of the person who slept below. Princes and persons of great wealth, when they founded monasteries, included, amongst the duties of the monks, that they should receive in them their earthly remains, and for ever make mention of the founders in their daily services. When the taste for founding monasteries declined, about the close of the 12th century, the disposition to secure the same object by the foundation of chantries began to prevail, and it continued with unabated zeal to the very eve of the Reformation, when all such foundations were swept away as superstitious.

A chantry did not necessarily require that any edifice should be erected for it; they were usually founded in churches already existing: sometimes the churches of the monasteries, sometimes the great cathedral or conventual churches, but very frequently the common parish church, whether in a town or in a rural district. All that was wanted was an altar with a little area before it, and a few appendages; and places were easily found in churches of even small dimensions, in which such an altar could be raised without interfering inconveniently with the more public and general purposes for which the churches were erected. An attentive observation of the fabric of the parish churches of England will often detect where these chantries have been, in some small remains, perhaps, of the altar, which was removed at the Reformation, but more frequently in one of those ornamented niches called *piscinas*, which were always placed in proximity with the altars. Sometimes there are remains of painted glass which it is easy to see has once been the ornament of one of these private foundations; and more frequently one of those arched recesses in the wall which are called Founders' Tombs, and which in many instances, no doubt, were actually the tombs of persons to whose memory chantries had been instituted.

In churches which consisted of only nave and chancel with side aisles, the eastern extremities of the north and south aisles were often used for these foundations; in the larger churches, having transepts, these were generally devoted to a similar use. In the great conventual churches and the churches of monasteries, it would appear as if provision had been expressly made for these private chantries in the original construction of the edifice, each window looking eastward being often made to light a small apartment just sufficient to contain an altar and a little space for the officiating priest.

It was by no means unusual to have four, five, or six different chantries in a common parish church; while in the great churches, such as old St. Paul's in London, the Minster at York, and other ecclesiastical edifices of that class, there were at the time of the Reformation thirty, forty, or fifty such foundations. When the fabric of a church afforded of itself no more space for the introduction of chantries, it was usual for the founders to attach little chapels to the edifice. It is these chantry chapels, the use and occasion of which are now so generally forgotten, which occasion so much of the irregularity of design which is apparent in the parish churches of England. Erected also, as they generally were, in the style of architecture which prevailed at the time, and not in accordance with that of the original fabric, they are a principal cause of that want of congruity which is

perceived in the architecture of different parts of the parish churches, but they contribute much to their picturesqueness.

When chapels were erected for the especial purpose of the chantries, they were usually also the places of interment of the founder and his family, whence we sometimes find such chapels belonging, even to this day, to particular families, and adorned with monuments of many generations. One of the most beautiful chapels of this kind is in the little village of Sandal, a few miles from Doncaster, the foundation of Rokeby, archbishop of Dublin, who died in 1521. The church of Sandal, being small, afforded no scope for the design of this magnificent prelate. Having, therefore, determined that here should be the place of his interment and the perpetual celebrations in his memory, he erected a chapel on the north side of the choir, open however to the church on one side, being separated from it only by open wainscot. On entering it by the door one sees at once the whole economy of one of these chapels. Under the window looking eastward an altar has stood; the piscina on the right remains. On each side of the east window is a niche where once, no doubt, stood an effigy of a saint whom the archbishop held in peculiar honour. In the centre is a brass indicating the spot in which the body of the prelate lies; and in the north wall is a memorial of him, having his arms and effigy, with an inscription setting forth his name and rank, and the day of his decease, with divers pious ejaculations. The stone- and wood-work have been wrought with exquisite care, and the windows appear to have been all of painted glass.

Chantries were sometimes also established in edifices remote from any church, a chapel being erected for the express purpose.

In chantries of royal foundation, or in chantries founded by the more eminent prelates or barons, the service was conducted sometimes by more than one person. But usually there was but one officiating priest. The foundation deeds generally contain a distinct specification of his duties, which consisted for the most part in the repetition of certain masses; but sometimes the instruction of youth and the delivering of pious discourses to the people made part of the duty of the chantry-priests. They also contain an account of the land settled by the founder for the support of the priest. The names of the persons whom he was especially to name in his services are set forth, as well as the mode of his appointment and the circumstances in which he might be removed. Generally the king was named together with the founder and members of his family. This, it was supposed, gave an additional chance of the foundation being perpetuated. The licence of the crown was generally obtained for the foundation.

In many towns and country places there are ancient houses known by the name of chantry houses, or sometimes chantries, or colleges. These have been places of residence of the chantry priests, and were called colleges, where they lived (a considerable number of them being in one church) a kind of collegiate life, it being held that the clergy should mix but little with the laity. These, as well as all other property given for the support of the chantry priests, were seized by the crown and sold to private persons, when, by the Statute 1 Edward VI. c. 14, all foundations of this kind were absolutely suppressed and their revenues given to the crown. An account had been taken a few years before of all the property which was settled to these uses, by the commissioners under the Act 26 Hen. VIII. c. 2, whose returns form that most important ecclesiastical document the 'Valor Ecclesiasticus' of King Henry VIII. The 'Valor' has been published by the commissioners on the Public Records, in five volumes folio.

CHAPEL (*capella*), a word common to many of the languages of modern Europe, and used to designate an edifice of the lower rank appropriated to religious worship. Its origin and etymology are very obscure.

In England it has been used to designate minor religious edifices founded under very different circumstances and for different objects.

1. We have a great number of rural ecclesiastical edifices, especially in the north of England, where the parishes are large, which are not, properly speaking, churches, *ecclesie*, though in common parlance they are sometimes so called, but are chapels, and not unfrequently called parochial chapels. Most of these are of ancient foundation, but still not so ancient as the time when the parochial distribution of England was regarded as complete, and the right to tithe and offerings determined to belong to the rector of some particular church. In the large parishes it frequently occurred that a family of rank which resided at an inconvenient distance from the parish church, would desire to have an edifice near to them, to which they and their tenants could resort for the benefit of Christian ordinances. On reasonable cause being shown, the bishop would often yield to applications of this kind; but in such cases he would not suffer the rights of the parish church to be infringed; no tithe was to be subtracted from it and given to the newly erected foundation, nor was that foundation to be accounted in rank equal to the older church, or its incumbent otherwise than an inferior and subordinate minister to the incumbent of the parish church. But the bishop generally, perhaps always, stipulated that there should be an endowment by the founder of such an edifice. Not unfrequently in edifices of this class there was the double purpose of obtaining a place of easier resort for religious worship and ordinances, and a place in which perpetual prayers might be offered for the family of the founder. [CHANTRY.] Others of these rural chapels were founded by the devotion of the parishioners. The population of a

village which lay remote from the church of the parish within whose limits it was included would increase, and thus the public inconvenience of having to resort to the parish church on occasion of christenings, churchings, marriages, and funerals, besides the services on the festivals, become great; they would therefore apply to the bishop in petitions, many of which are to be found in the registers of the sees, setting forth the distance at which they lived, the impediments, constant or occasional, in the way of their ready resort to the parish church, as want of good roads, snow, the rising of waters, and the like, on which the ordinary would grant them the leave which they desired, reserving, however,—as seems almost always to have been the case,—whatever rights and emoluments had beforetime belonged to the parish church. In the parish of Halifax there are twelve of these chapels, all founded before the Reformation. In the parish of Manchester, and in most of the parishes of Lancashire, such subsidiary foundations exist in great number. Those foundations of this class which could be brought within the description of superstitious foundations, were dissolved by the Act 1 Edward VI. c. 14, for the suppression of chantries; but while the endowment was seized, it not unfrequently happened that the building itself, out of the piety of the person into whose hands it passed in the sale of the chantry lands, or the devotion of the persons living near it and long accustomed to resort to it, continued to be used for the reformed worship, and remains to this day a Christian church, the incumbent being supported by the casual endowments of the period since the Reformation, and especially by what is called Queen Anne's Bounty, in which most of the incumbents of chapels of this class have more or less participated.

2. The term chapel is used to designate those more private places for the celebration of religious ordinances in the castles or dwelling-houses of distinguished persons. We find in the fabrics of some of the oldest specimens of the castles of England some small apartment which has evidently been used for the purposes of devotion, and this sometimes in the keep, the place of last resort in the time of a siege. A remarkable instance of this is at Conisbrough, in Yorkshire. But in castles of the time of Edward I. and subsequently, chapels of this kind were erected adjoining the apartments appropriated to the residence of the family. Most of the baronial residences, it is probable, had chapels of this kind, and how splendid they sometimes were we may see in St. George's Chapel at Windsor.

3. The chapels of colleges, as in the two universities; of hospitals, or other similar foundations.

4. Chapels for private services, chiefly services for the dead, in the greater churches, as the chapel of St. Erasmus, and others, in the church of Westminster. Additions made to the parish churches for the purpose of chantries are sometimes called chantry chapels.

5. Places of worship of modern foundation, especially those in towns, are called chapels of ease, being erected for the convenience of the inhabitants when they have become too numerous for the narrow limits of their parish church. Many of these have had districts assigned to them with cure of souls, and the right of celebrating baptisms, marriages, &c., under the provisions of special Acts of Parliament, in which the rights and duties of the incumbent and the founders are defined.

6. The word chapel is pretty generally used to denote the places of worship erected by Dissenters, though the Quakers and the more rigid of some religious denominations, out of dislike to the nomenclature of an ecclesiastical system which they do not approve, prefer to call such edifices by the name of meeting-houses.

CHAPLAIN, *capellanus*, a word formed immediately on the word chapel, *capella*, according to one of the commonest analogies of our language.

A chaplain is properly a clergyman officiating in a chapel in contradistinction to one who is the incumbent of a parish church; hence the clergymen appointed to the army and navy are called chaplains, as well as those performing duty in union workhouses. But its more frequent use is now as designating clergymen who are either residing in families of distinction and actually performing religious services in the family; or who are supposed to be so, though not actually so engaged. This fiction proceeds on the assumption that every bishop and nobleman, with some of the great officers of state, have each their private chapel, to which they nominate a priest, or more than one. Certain privileges respecting the holding of benefices belong to these chaplains, by reservation out of the Act against Pluralities 21 Hen. VIII. c. 13. The power of appointment in the sovereign is unlimited; the number of chaplains which noblemen and other persons may nominate is fixed: an archbishop may have eight; a duke or a bishop, six; a marquis or earl, five; a viscount, four; a baron, knight of the garter, or the lord chancellor, three; the treasurer of the king's house, the comptroller of the king's house, the clerk of the closet, the king's secretary, the dean of the chapel, the almoner, and the master of the rolls, may each nominate two; the chief justice of the Queen's Bench and the warden of the Cinque Ports, each one; a duchess, marchioness, countess and baroness, being widows, are allowed to nominate each two.

CHAPTER. The canons in the cathedral or conventual churches, when assembled, form what is called the chapter, *capitulum*, anciently the council of the bishop. [CANON.] Other religious communities, when assembled for business, sat in *chapter*. Attached to many cathe-

dral and conventual churches are buildings for the meeting of the chapter, called chapter-houses. The buildings of this kind connected with Westminster Abbey and York Minster, are octagonal and of singular beauty. [CHURCH.]

The members of the College of Arms, that is, the heralds and pursuivants, are said to hold a *chapter* when they sit together to confer on the business of their office.

CHAPTER-HOUSE. [CHURCH.]

CHARACTERISTIC (of a logarithm). The whole number, positive or negative, which precedes the decimal point of a logarithm. The reason of this number having a separate name is, that in Briggs's system it is so easily found as not to form a part of the tables. [LOGARITHM.] In truth, it ought to be called the *characteristic* of the primitive number of the logarithm; and the following theorem should be announced,—The characteristic of a number is the integer portion of its logarithm.

CHARADE, a species of riddle, in which a word consisting of several syllables is indicated, first by an enigmatical description of each syllable, taken separately, and then by a similar description of the whole. It does not seem to be necessary that the word should consist only of two syllables, according to the definition given in most of our English dictionaries and cyclopædias. To have anything of wit or point, a charade should be so contrived, that the ideas employed to denote or suggest the several syllables, and the entire word, shall be all in some way connected together, or arise naturally the one out of the other. This however is often neglected. The following, which we find in the late editions of the dictionary of the French Academy, is not a bad example of a true charade: "My first makes use of my second to eat my whole;" the translation being the word *chiendent* (dog's grass). The word charade is said to be derived from the name of the inventor of this particular species of enigma. Some of the best specimens of this kind of exercise of ingenuity were written in verse by the late Winthrop Mackworth Praed, and appeared originally in Knight's 'Quarterly Magazine,' where they were called enigmas. The term appears to be originally French, and not to have come into use till towards the end of the last century.

CHARCOAL is the impure carbon obtained by the decomposition of vegetable matter by heat without free access of air; during this operation the more volatile elements of the woody fibre are expelled as new compounds, while the carbon the fixed ingredient, remains, mixed however with some saline matter, presently to be noticed, which renders it impure.

What occurs during the preparation of charcoal will be readily understood by referring to the analysis of woody fibre by MM. Gay Lussac and Thénard, who found, whatever be the kind of wood employed, that after drying at 212° Fahr. it yielded upon an average—

Carbon	52
Hydrogen	5.3
Oxygen	42.7
	100.0

Now as the oxygen and hydrogen are almost exactly in the proportions required to form water, it would appear that if these only could be expelled by heat, the products of the decomposition would be carbon and water. We shall, however, presently mention, that owing to the combination of a part of the carbon with these elements, and also of the oxygen of the air, the compounds which arise from the decomposition of wood are much more complicated, and are of very great importance.

The making of charcoal for domestic uses, and probably also for such manufacturing or metallurgic processes as the ancients were acquainted with, is of high antiquity. Pliny (lib. 16, c. 6) mentions that the wood was formed into a pile, the top of which was covered with clay; evidently to prevent the access of too much air, by which, as experience had no doubt taught, it was found that the wood was converted entirely into ashes.

Charcoal is now prepared by two different methods: one, resembling in principle that just mentioned, consists in piling the wood in a heap, which is covered with turfs and sand to allow of the entrance of such a portion only of atmospheric air as is sufficient to carry on the imperfect combustion required. The heap is fired at several holes left near the bottom, and a draught of air is obtained by at first leaving an orifice at the top of the heap; this is afterwards covered, and when it is found that the flame has pervaded the heap entirely, the bottom holes are also closed. When the mass has cooled, the charcoal remains.

Within a comparatively few years another method of obtaining charcoal has been adopted, by which the article obtained is said to be better adapted for the purpose of making gunpowder. This is done by putting the wood into iron cylinders, which are set in brickwork and surrounded by fire; the wood in the cylinders has no communication with the external air, and they have only a small opening to allow of the escape of the gaseous products arising from the decomposition of the wood, and the new compounds derived from the combination of its oxygen and hydrogen with a portion of the carbon.

These products, or at least those which are condensable, are chiefly water, tar, impure acetic acid, usually called pyroligneous acid [ACETIC ACID], creosote [CREOSOTE], pyroxylic spirit [PYROXYLIC SPIRIT], and

empyreumatic oil. One hundred parts of oak wood dried in the air yielded 43 of pyroligneous acid, about 4.5 parts of carbonate of potash, 9.06 parts of empyreumatic oil, and 26.2 of carbon; different woods yielded somewhat varying proportions of these substances, but the oak gave the largest quantity of charcoal.

Although the charcoal thus procured is preferable for making gunpowder, yet it is stated that it is not so well liked for many other purposes; it is also said to be much lighter than that made in the usual way, and this appears to occasion some variation in the degree of heat required for its consumption in a given time, and thus influences many operations. The densest charcoal gives the most heat while burning.

The general properties of charcoal are, that it is black, sonorous, and brittle, and retains the form of the wood from which it is obtained; it is insoluble in water; infusible and fixed in the most intense heat ever produced. It is a very bad conductor of heat, but conducts electricity. Its property of condensing various gaseous bodies has been already noticed, as well as the compounds which it forms with some other elements. It has considerable antiseptic powers. [CARBON.]

It has been mentioned that certain impurities exist in the charcoal of wood; thus when 100 parts of old oak wood are entirely burnt, there remain about 5 parts of ashes, and different woods furnish very different proportions of them; these ashes are principally carbonate of potash [POTASSIUM], unquestionably derived from the decomposition of some salt containing a vegetable acid, as the tartaric or malic. It has been thought that the spontaneous combustion which charcoal has been known occasionally to undergo, has been occasioned by a portion of potassium having been reduced to its metallic state, and the subsequent action of moisture upon it. For an account of the different quantities of charcoal and ashes obtained from different kinds of wood, see Dumas, 'Traité de Chimie,' tome i. p. 558; and see also in 'Phil. Mag.,' vol. iii., a paper by M. Mushet, on the same subject.

CHARCOAL, ANIMAL. [BONE BLACK.]

CHARGE, in the practice of artillery, denotes the quantity of powder placed in a gun, howitzer, or mortar, for the purpose of expelling the shot or shell by its explosion.

The service-charge varies from one-sixth to one-third of the weight of the projectile: the lower charges being used in the field, or in naval actions; and the higher in breaching the walls of fortresses. It is evident that extensive ranges and great velocities of shot are not required when artillery is directed against an enemy's columns or lines; and it is found by experiment that a ball which just pierces the timbers of a ship will fracture them more than if it passed rapidly through them. On the other hand, the greatest momentum is necessary on commencing the formation of a breach in a rampart faced with brick or stonework, as the depth to which the shot will penetrate is thereby increased; and therefore the highest charges are then required.

According to Dr. Hutton (Tract 34), different charges of powder, when the weight of the ball remains the same, produce velocities which are as the square roots of the weight of powder; and when the weight of powder is the same while that of the ball varies, the velocities are inversely proportional to the square roots of the weight of the balls. The Doctor states, also, that the greatest velocities are produced in guns, the lengths of whose bores are equal to fifteen, twenty, and thirty calibres, or diameters, by charges occupying $\frac{1}{15}$, $\frac{1}{20}$, and $\frac{1}{30}$ of the lengths of the bores respectively; and he adds, that by increasing the quantity of the charge, the velocities increase till they amount to a certain value, after which they decrease till the bore is quite filled with powder. The charge producing the maximum velocity is greater as the gun is longer; but it does not increase in so high a ratio as the length of the gun.

CHARGE D'AFFAIRES, one who transacts diplomatic business at a foreign court during the absence of his superior, the ambassador. The agents that bear this name also form a separate class, being the chosen envoys or residents at the states to which other states do not appoint diplomatists of the higher grades. In this capacity the *Chargés d'Affaires* act for themselves, represent their country, and are independent of any ambassador. In the ordinary routine and course of promotion, the secretary of legation, or secretary of embassy, becomes a *Chargé d'Affaires*. For their privileges and duties see AMBASSADOR. In this year (1859) the British *Chargés d'Affaires* on the diplomatic list are all those to the various republics of South America, and to the empire of Morocco.

CHARIOT, a light sort of coach; also, a car (*currus*), in which men of arms were placed in fight. The name is derived from the French word *charrette*. Cars or chariots are of very early use. The invention of them was attributed by the Greeks to Minerva (Hom. 'Hymn. in Ven.' v. 12), on which account she was venerated at Athens and various other places in Greece under the name of Hippias; and the honour of the invention was shared by Erichthonius, who, according to Virgil, was supposed to have first harnessed horses to a car, and to have introduced chariot-races at the Panathenæa which were established by him. The ancient chariot had but two wheels, and was open overhead. It appears to have been usually drawn by two horses, but in races three and even four horses were not uncommonly yoked to it. Of the Roman *biga*, or two-horsed chariot, a representation is given under BIGA. The three-horse chariot was called a

triga, one of four-horses a *quadriga*. The war chariot carried two persons, one of whom was the driver, who stood in front. The chariots used by the Romans in their public games only carried the driver. The race chariots were often very richly adorned. The

[Chariot Race, from a bas-relief in the British Museum.]

most splendid of the Roman chariots were, however, those employed in triumphs. The funeral chariot was also adorned in a very costly manner.

[Funeral Chariot, from a bas-relief in the British Museum.]

The most ancient war-chariots we know of are those of Pharaoh, which were overwhelmed in the Red Sea. (Exod. xiv. 7.) The Canaanites whom Joshua engaged at the waters of Merom had a multitude of chariots. (Josh. xi. 4.) And the Philistines, in their war against Saul, are stated (1 Sam. xiii. 5) to have had thirty thousand chariots.

Chariots armed with scythes were in use for many ages in all the Eastern countries; and were regarded as a principal arm of war. Such are mentioned in the Second Book of Maccabees (xiii. 2), which the king of Syria led against Judæa. They were used by the Persians, as we see from Xenophon ('Anab.' i. 8); and they constituted a remarkable feature in the armies of the ancient Britons. Cæsar ('De Bell. Gall.' v. 19) says, that after Cassivellaunus had dismissed all his other forces, he had still four thousand of these war-chariots about his person. See Cæsar's account of the method used in fighting with them (iv. 33).

The *Essedum* and the *Rheda* were among the Roman war-chariots of the larger size. Greek and Roman chariots frequently occur on the reverses of medals. The modern chariot is a mere coach-maker's modification of the ordinary private coach or carriage.

CHARITABLE USES. [USES, CHARITABLE.]

CHARITIES. [USES, TRUSTS.] By the Charitable Trusts Act, 1853, a body of commissioners has been created for England and Wales, with power to inquire into all charities, their nature, objects, and administration, and the condition of the property belonging to them; to require the production of accounts and documents from the trustees of charities, and to cause inspectors to visit and report on their management. No proceeding with reference to any charity can be taken by any *relator* without the sanction of this board, which is called "The Charity Commissioners for England and Wales;" the attorney-general alone may proceed by *ex officio* information. The board may direct in what court proceedings for the administration of any charity are to be taken; but where the income is under 30*l.*, the county court of the district, or the court of bankruptcy of the district, in which the charity is situated, has jurisdiction. In other cases the

court of chancery must be resorted to. The statute does not extend to Scotland or Ireland, to the Universities, or the city of London. A report of the proceedings of the board must be annually laid before Parliament.

CHARLES'S WAIN, a name for the Great Bear [*URSA MAJOR*]. This constellation was also formerly called "the brood hen," in England. (Robert Recorde, 'Castle of Knowledge.') This constellation was sometimes called a waggon, both by the Arabs and Romans; but who Charles may have been we have no means of knowing, not having an English Hyginus of sufficient antiquity to be authority as to this personage.

CHARON, son of Erebus, was the fabulous boatman who conveyed the shades of the departed across the rivers which girt the infernal regions. (Eurip. 'Alcest.' 253, 441; Aristoph. 'Ran.' 202; Virgil, 'Æneis,' v. 298.) His fare was an obol (the sixth part of a drachme), which was laid in the mouth of a person about to be buried, in order that he might have wherewith to pay the freight. (*ναῦλον, δανάκη*. Aristoph.; J. Pollux, ix. 82; and Juvenal, iii. 267.) Charon does not appear in Homer; his origin is referred to Ægypt (Diodor. i. 90), where he had a representative in Amenthes, the emblem of a future state: his name is thought to point to the joy produced by a freedom from sublunary troubles. (See Creuzer, 'Symbolik.' i. p. 341.)

CHART, or **SEA-CHART**, a hydrographical map, or a projection of some part of the sea, *in plano*, for the use of navigation. Fournier, in his 'Hydrographie,' (fol. par. 1667, p. 505,) ascribes the invention of charts to Henry, son of John, king of Portugal; certain it is that marine charts appear first to have issued from the Portuguese. Bagford says, the first step that was made toward a knowledge of our own coasts was by an almanac, with a chart of the coasting part of England, printed on vellum or parchment, by Wynken de Worde, 1520, and bound in a small portable volume. This was the first he had seen of the kind. (See Bagford's 'Letter to Hearne,' prefixed to Leland's 'Itinerary,' vol. i. p. lxxx., and 'Spicileg. ad Gul. Neubrig,' p. 749.) John Rotz, a native of Dieppe, and servant to King Henry VIII., made for the king's use a Book of Hydrography, so called, being an account of the compass, elevation of the pole, latitude, sea coasts, &c., 1542, finely painted on eighteen very large skins of parchment, still preserved among the royal manuscripts in the British Museum, marked 20 E., ix. Of this description also is a very curious chart, preserved in the same collection, formerly belonging to Lord Oxford, and probably of as early, if not an earlier date than Rotz's charts. New Holland is laid down upon it as an island, under the name of Java le Grand. The writer of the present article, many years ago, consulted the late Captain Flinders for his opinion whether this portion of the chart could have been laid down from actual observation. The answer was, "Most certainly; for lines of red dots are made to border the coast exactly to the extent to which it is coral-bound, and no farther; I was wrecked upon one of those reefs, and have reason to remember them." The names of places are occasionally given upon the different shores in this chart, in French; and the very spot upon which Captain Cook afterwards named Botany Bay is designated as *Côte des Herbages*.

The generality of the early Portuguese charts seem to have been made toward the close of the 15th century. Through the encouragement given by the Board of Admiralty, excellent surveys have of late years been made of our own and many foreign coasts. But the increased speed of steamers bears obviously upon the question of *extreme accuracy* in charts, with a force which the hydrographic department of the Admiralty seems fully to appreciate. It is worthy of consideration whether the establishing of a systematic scheme of *colouring the soundings* on what may be called "pilot charts," so as to indicate equal depths of water by the same shade of colour, would not more rapidly convey useful information thereupon; such information as would take firmer hold upon the memory.

For instance, and as a system adapted to navigation, all depths under 10 feet at low-water spring tides might be left the colour of the paper of the chart. The various shallows occurring in this space would at a glance be known at once by the ordinary method of "dotting;" indeed, if advisable, a dotted line indicating "one fathom" might, as at present, be continued for the convenience of vessels of very light draught of water.

Between 10 feet depth and 20 feet might be coloured pale, but distinct, yellow. (chrome yellow.)

"	20	"	"	30	"	"	pale carmine.
"	30	"	"	40	"	"	deeper carmine.
"	40	"	"	50	"	"	pale sepia.
"	50	"	"	60	"	"	deeper sepia.
"	60	"	"	70	"	"	pale neutral tint.
"	70	"	"	80	"	"	deeper neutral tint.
"	80	"	"	90	"	"	pale purple.
"	90	"	"	100	"	"	deeper purple.

Further colouring on pilot charts would be unnecessary; but as the subject of the introduction of the submerged telegraph cable is in its mere infancy, and future discoverers may very probably produce cheaper cable and apparatus, leading to the more extended adoption of telegraphic communications across narrow estuaries or channels, it might soon be found advisable to adopt a mode of colouring to *greater depths* of water. In such case, all would soon be accomplished with-

out chance of confusion by adding a cypher to the above figures, retaining the same gradations of colour and carrying us on to 1000 feet.

It will be seen from the above, that coasting vessels will have to regard principally the pale yellow and uncoloured soundings, while larger ships would only have in most cases to regard the pale carmine, except when anchorage became the question, when the ordinary figures indicating soundings would be available as at present. Nothing that could simplify navigation should in these days be rejected.

Nor is it unimportant that fishermen upon our coasts, seeing (at a glance on such charts) the holes and deeps and conformations at the bottom of the sea, and knowing traditionally the habits of their prey, might thus be directed to more successful captures.

By attention to this colouring of charts some curious geological deductions would doubtless result. As an example: The writer's first impression on seeing a chart of the entrance to the Thames thus coloured by him for his amusement, was, that at a distant period the "River Thames" lay entirely northward of a line which may be drawn from the Long Sand Head to the "Shivering Sand," thence to the "East Cant," thence to the "Cant," and thence to "Garrison Point," Sheerness. That the space between this said line and another drawn from near the Long Sand Head on the eastward of the present Long Sand, and trending southward, passing to the eastward of the Margate Sand, and joining the mainland eastward of the Reculvers, *formerly inclosed dry land, constituting an extensive promontory of Kent.* It would thus seem probable that the "Prince's" and "Queen's" channels are of comparatively recent formation, originating in the denudation of the soft strata of the tertiary from what is now the Margate Sand, and the large area of the "Flats" off Whitstable; thus forming a new eastern entrance to the Thames by the "West Girdler," and in process of time washing the coast-line into its present form. *This work is even at the present day progressing;* and few, having a knowledge of this fact, and being aware of the nature of the tertiary formation, would on inspecting a chart *carefully coloured as to soundings*, doubt the *general accuracy* of the above.

As a further instance, we may even take the case of the Goodwin Sands, on the east coast of Kent. On seeing a coloured chart hereof, geological intimations and inferences are very striking. What do we find? An easy curve in the soundings, originating about two miles off the South Foreland, trending first towards the north-east, then northerly, and afterwards with an easy bend towards the north-west, marks the general line of the outer edge of the Goodwin, and lying, at its greatest distance, about 7 miles from (say) Deal, inclosing a space gradually shallowing towards the North Foreland, and embracing within its limits such inequalities of surface—known as the "Brake" sand, and sundry "knolls"—as one would suppose the action of the sea upon strata of such varied compactness and density as the "tertiary" would cause. On the outer edge of the Goodwin range, especially in the part exposed to the full action of the flood-tide from the English Channel, as accelerated by the narrowness of the Straits of Dover, we find as much as 30 or 40 fathoms of water. The return action of the ebb-tide seems, in its influence upon the North Goodwin Head, to have met with resistance from the chalk foundation on which the Goodwin Sands are known to rest. It is extremely probable, therefore, that chalk would be found at the "Goodwin knoll" a *very few* feet from the surface. Now, who will say that the "curve," as intimated in the coloured chart and alluded to as passing the outer Goodwin and returning easily towards the North Foreland, was not once the general coast-line of East Kent? Tradition tells us of the territories of Earl Goodwin in the time of Harold II., as it will some day point to a shoal on which "stood" the present Sandown Castle. History even points vaguely to the destruction and submersion, or "*overwhelming*," of the lands of Earl Goodwin. [KENT, in GEOG. DIV.] The same destruction is at the present day assailing Sandown Castle; it was only built in the reign of Henry VIII., but has already yielded its moat and outworks to its powerful assailant. One might, on seeing a coloured chart of the district, even go further, and declare that the flood-tide from the British Channel, gathering force as it sweeps the French coast past Cape Grisnez, strikes in a direct line towards the inside of the Goodwin or through the present Downs in such a manner as to account for the complete denudation of the strata along the east coast of Kent; and if any further proof of this abrasion be wanting, the *débris* has evidently been deposited along the coast opposite the North Foreland, forming the well-known *plateau* around it of from 6 to 7 miles diameter, and on which at most is found about 50 feet of water. The subject is interesting as important, especially as it requires some such considerations as the above to account for the vast results of a once moving water-power which once formed the chalk "cliffs" of Albion in their now *scarcely perceptibly* changing aspect. The comparative shallowness of the sea off the North Foreland is otherwise an obstacle to other attempts at elucidation; for it seems reasonable to suppose that the former action of *deep* water, and the then unchecked rush of flood-tide from Cape Grisnez, could alone have produced such stupendous results.

If anything can further justify a recommendation to colour charts of the coast, it may be the following, as indicating its tendency towards a creation of new ideas on certain subjects: Sandown Castle (above referred to), has been within the memory of living men,

gradually and visibly suffering from the encroachment of the sea; while the celebrated Richborough Castle, only about five miles from it, and which in the time of the Romans (say 1800 years ago), was washed by the sea, now stands two full miles inland.

Antiquaries have sought all means whereby to reconcile this anomaly. But may we not again revert to the circumstance of the south-east coast of Kent, having been at one time so great an obstacle to the course of the channel flood-tide, as to have been gradually "scooped away" by the waters, until probably the sea reached the chalk barrier of the Isle of Thanet, which now ends at Pegwell Bay. On its approaching this limit, there being perhaps in those days much less room for the passage of the flood-tide inside the present Goodwin, the force of the tide into this "bight" or excavation, or narrow channel, would have considerably raised the level of high water above the adjacent shore, and have overflowed the marsh-land even to Richborough, forming at the same epoch the stream which insulated Thanet. History, in vague and dark traditions, acquaints us, however, that some 800 years after, a mighty storm or irruption of the sea overwhelmed the lands of Earl Goodwin (as already noticed). Now it is curious to consider the probability of this irruption having been nothing less than the bursting of some barrier of sand or strata, which by admitting the flood-tide in its less obstructed flow, drained the land at Richborough Castle, and reduced the "Wantsume," which insulated Thanet (and which from having in very early times been three or four miles wide, had in the year 700 gradually decreased to about half a mile), to the mere ditch of the present day.

We have an instance of this raising of the tide level, in the daily action of the sea in the Solent, and the causes which give to Southampton *twice highwater* in the same tide.

Such considerations may at first appear to be out of place under our word "chart," but knowledge springs from unexpected sources. An apple, a frog's leg, thoughts on a "pebble," each in its way has proved a lamp to the learned. A mere taper may enlighten Truth's magazine, and by its means we may pluck the rich and varied fruits of investigation, even from the dust of the air,—from a ray of light,—*why not from a tinge of colour in a wash of "carmine," or a streak of "sepia," or a stroke of "neutral tint"?*

The particular species of charts most used at sea will be explained under the head MERCATOR'S PROJECTION. See also MAP, and STEREOGRAPHIC, ORTHOGRAPHIC, GNOMONIC, and CONICAL PROJECTIONS, under which last head will be given Flamsteed's and the modern French projections.

CHARTÉ, from *charta*, "paper," though in its generic sense embracing every kind of legal instrument, has been restricted by modern usage, and signifies any ancient title-deed; but the name was given to the letters of franchise granted by the kings of France during the middle ages to several towns and communities, by which they were put in possession of certain municipal rights or privileges, such as the free election of their local magistrates, &c., a custom, according to Hallam ('Europe during the Middle Ages,' vol. i.), dating from the time of Louis VI., and becoming of almost universal application in France by the end of the 13th century. At present the word *charte* is used in France to signify the solemn acknowledgment made by Louis XVIII. on his restoration in 1814 of the rights of the nation, which was the fundamental law of the French constitutional monarchy, in principle somewhat resembling that of the English constitution as founded on Magna Charta and the Bill of Rights. By it the legislative power was vested in two chambers, peers and deputies, subject to the king's sanction. The former being composed of peers nominated by the crown, and holding either life or hereditary peerages as the crown might please; the latter comprising deputies whose age was to be at least 40, paying 1000 francs to the direct taxes, and nominated by electors of at least 30 years of age paying 300 francs to the direct taxes. All laws were to be promulgated by the king, the executive power being vested solely in him, who was to appoint to all the offices of the administration, both civil and military, and to have the command of all the military and naval forces. He also was to appoint the judicial officers, who, however, when once appointed were irremovable by him. The king was to make all treaties of peace, alliance, or commerce. His person was to be inviolable; but the ministers were to be responsible. One article of the *Charte*, having given occasion to a false interpretation, of which the ministers of Charles X. availed themselves to issue the famous ordonnances which gave rise to the revolution of July, 1830, was altered on the accession of Louis Philippe, and it was clearly explained that "the king issues the necessary ordonnances and regulations for the execution of the laws, without having the power in any case to suspend the course of the law or to delay its execution." The *Charte*, with this and one or two more modifications of minor importance, was sworn to by Louis Philippe on the 9th of August, 1830. Subsequently, a change was made by the legislature in the constitution of the Chamber of Peers, the peers being for life, and the peerage not being hereditary in their families.

The *Charte* consists of sixty-nine articles, and is inserted in the *Almanac Royal et National*; the principles of it are given in Alison's 'History of Europe, from the Fall of Napoleon,' vol. iv.

The system of law introduced by this charter remained in full force until the revolution of 1848, by which the government of Louis Philippe was overthrown and the republic instituted. On the acts of

that government, short lived and unacceptable to the French people as events seemed to prove, it is unnecessary to dwell; nor need we do more than advert to the rapid and startling changes by which the administration of affairs was surrendered to one individual, and the form of government altered from a republic one and indivisible, to an empire absolute and uncontrollable. But between the acts of that drama, the downfall of the republic and the elevation of the empire, a new constitution was promulgated on the 14th of January, 1852, preceded by a proclamation addressed to the French people, in which the principles of the Revolution of 1789 were emphatically appealed to, and the Constitution of the year viii. of the Republic, with the Napoleonic modifications, relied upon as the foundation of the new system. The constitution thus proclaimed contains eight chapters, in the first of which the announcement of the constitution is solemnly made; in the second, the forms of the government are stated; in the third, the position and duties of the president are fixed; in the fourth, fifth, and sixth, the senate, the legislative body, and the council of state are defined; in the seventh, the high court of justice is described; and the eighth contains certain general and transitory provisions. To this constitution a decree was added, consisting of thirty-four articles, constituting and regulating the council of state; and on the 22nd of January, sundry other decrees appeared, by one of which an office called that of minister of state was established, whose functions were carefully defined. A decree of the 22nd of March was promulgated, with the view of describing the relations of the senate and legislative chamber to the council of state, and securing the harmonious action of these three bodies. Finally, on the 23rd of December, 1852, another decree, or rather *senatus consultum*, appeared, by which Napoleon, by the grace of God and the national will, emperor of the French, explained and modified the Constitution of January 14th, 1852. For the particulars of this document, as well as those above-mentioned, the reader is referred to the 'Annual Register' for the year 1852.

CHARTER. This word is from the Latin *charta*, a word of uncertain origin: the Greek form of the word is *chartes* (*χαρτης*). *Charta* appears to have signified writing-material made of papyrus. The term was afterwards applied, not only to the materials for writing, but to the writing itself, as to a letter or the leaf of a book. In English law it was used to denote any public instrument, deed, or writing, being written evidence of things done between man and man, and standing as a perpetual record. (Bracton, lib. 2, c. 26.) Among the Saxons such instruments were known as *gewrite*, or writings.

Charters are divided into: 1. Charters of the crown; 2. Charters of private persons.

1. Royal charters were used at a very early period, for grants of privileges, exemptions, lands, honours, pardon, and other benefits that the crown had to confer; and thus the term became restricted to such instruments as conferred some right or franchise. These instruments did not differ in form from letters patent, being usually addressed by the king to all his subjects, and exposed to open view, with the great seal pendent at the bottom; but such as contained grants of particular kinds were distinguished by the name of charters. Thus, as giving was the object of a charter, the term became very popular, and was used in a more extended sense, to denote laws of a popular character.

Whatever may have been the prerogatives and legislative authority of the kings of England, it is certain that from the earliest times there were many rights and liberties which by the law of the land belonged to the people. As these were often restrained and violated, nothing was more acceptable to the nation than a formal recognition of them by the crown; and the popular name of charter was applied to those written laws by which the kings from time to time confirmed or enlarged the liberties of the people. Such laws were regarded, not only as concessions from the king, but as contracts between man and man—between the king and his subjects; while, at the same time, they were promulgated as the legislative acts of the sovereign authority in the state.

The charter of William the Conqueror, for observing the laws throughout England, was in the nature of a public law. It settled the religion of the state, and provided for its peace and government, for the administration of justice, the punishment of criminals, and the regulation of markets; it confirmed the titles to lands, and the exemption of the tenants in chief of the crown from all unjust exaction and from tallage. The words are those of a lawgiver appointing and commanding; "*statuimus*," "*volumus et firmiter precipimus*," "*interdicimus*," "*decretum est*," are the expressions by which matters are ordered or prohibited. (Fœdera Rec. Comm. Ed., vol. i. p. 1.)

The charters of liberties granted by Henry I., Stephen, Henry II., John, Henry III., and Edward I. are all, more or less, in the nature of public laws, either making new provisions, or confirming, enlarging, and explaining existing laws, and relate to the freedom and good government of the people, and all the most important interests of the country. Some of them are still regarded as authoritative declarations of the rights and privileges which the people of England have enjoyed for centuries. So valid and binding were the royal charters considered, that in the 37 Hen. III. (1253), in the presence of the king, several of the first nobles, "and other estates of the realm of England," the archbishop and bishops, excommunicated and accused all who should violate or change "the Church's liberties or the ancient approved

customs of the realm, and chiefly the liberties contained in the charters of the common liberties and of the forest, granted by our lord the king." In those times no sanction more solemn could have been given to the authority of any law. It was intended chiefly as a check upon the king himself, whose power had been restrained by the popular concessions made in the charters of liberties; but it was also directed against all his subjects who should violate the liberties of the people. [*MAGNA CHARTA.*]

These charter-laws, though often expressed to have been made by the advice of the king's council, implied an absolute legislative power vested in the crown; and as royal prerogative became restrained and the public liberties enlarged, legislation by charter was gradually superseded by the statutes and ordinances made in parliament. During the reigns of Henry III. and Edward I. laws were promulgated in both forms; but since that time statutes and ordinances have been the only records of legislation—not differing materially, at first, either in form or in the nature of the authority from which they emanated, from the charters of earlier reigns, but gradually assuming their present character as acts agreed to by the entire legislature.

But notwithstanding the discontinuance of the practice of promulgating general laws by royal charter to bind the whole kingdom, the exercise of prerogative, by means of charters, has partaken of a legislative character throughout the entire history of the British government. Some of the most ancient and important of these were charters to boroughs and municipal bodies, conferring immunities and franchises, of which the greatest was that of sending representatives to parliament. There are still extant municipal charters of the Saxon kings, and of the Norman kings after the Conquest, conferring various rights upon the inhabitants of boroughs, of which an exclusive jurisdiction was always one; but the first charter of incorporation to any municipal body appears to have been granted in 1489, in the reign of Henry VI., to Kingston-upon-Hull; although, in the absence of prior charters, it has been usual to presume that charters confirming existing usages had been lost.

Between the reigns of Henry VIII. and Charles II. no less than 180 members were added to the House of Commons by royal charter, the last borough upon which that right was conferred in this manner having been Newark, in 1673. Several of these were ancient boroughs which had ceased to send members, and whose rights were thus restored by charter; while some towns, expressly created boroughs by charter, did not send members to parliament for centuries afterwards, as Queenborough, for example, to which a charter was granted in 1368, but which did not return members until 1578. Hence it has been argued that, notwithstanding the practice of later reigns, the charter of the crown alone was not sufficient in law to entitle a town to send members to parliament, although expressly created a borough, to which, by the common law, the right of sending members was incident. This view derives confirmation from the acknowledged law that the crown was unable, by charter, to exempt a borough from returning members, since that right was always held to be exercised for the benefit of the whole realm, and not for the advantage of the particular place. Upon these grounds, a charter of exemption to the citizens of York was declared void by Act of Parliament, 29 Henry VI. c. 3. But as parliamentary representation, after having been made the subject of legislation by parliament under Henry VIII., has now been comprehensively arranged for the whole kingdom by Statute, the legal effect of royal charters upon the elective franchise has become a question merely of historical interest. The peculiar rights of corporations have also been determined by the Municipal Corporations Act (5 & 6 Will. IV. c. 76), which has since its passing been amended by a long series of statutes. A power is reserved to the crown, with the advice of the privy council, to grant charters of incorporation to other towns, upon the petition of the inhabitants, and to extend to them the provisions of the Act.

Charters were formerly granted by the crown which established monopolies in the buying, selling, making, working, or using certain things; an injurious practice, contrary to the ancient and fundamental laws of the realm, which was abolished by 21 James I. c. 3. [*MONOPOLY.*]

The crown has ever exercised, and still retains, the prerogative of incorporating universities, colleges, companies, and other public bodies, and of granting them, by charter, powers and privileges not inconsistent with the common law. But as the most considerable bodies ordinarily require powers which no authority but that of parliament is able to confer, such corporations as the East India Company and the Bank of England, which were originally established by royal charter, have long since derived their extraordinary privileges from Acts of Parliament, as well as other public companies which have been incorporated in the first instance by statute.

But the largest powers now conferred by royal charter are those connected with the colonies and foreign possessions of the crown. Whenever a new country is obtained by conquest or treaty, the crown possesses an exclusive prerogative power over it, and by royal charters may establish its laws and the form of its government; may erect courts of justice, of civil and criminal jurisdiction, and otherwise provide for its municipal order, for raising its revenue, and the regulation of its commerce. This power of the crown, however, is always subject, through the responsibility of ministers, to the ultimate control

of parliament; and if once deputed to a legislative assembly or other local government, possessing rights and liberties defined by charter, cannot be recalled.

2. Charters of private persons are the title-deeds of lands, many of which are the ancient grants of feudal lords to their tenants. These pass with the land as incident thereto, and belong to him who has the inheritance, or, if the land be conveyed to another and his heirs, the charters belong to the feoffee. A charter of the crown, granted at the suit of the grantee, is construed most beneficially for the crown, and against the party; but a private charter is construed most strongly against the grantor.

CHARTER-HOUSE, London. Sir Walter de Manny, knight, a stranger born, lord of the town of Manny, in the diocese of Cambray, in the Netherlands, who for services rendered to King Edward III. was made one of the first knights of the order of the garter, in the year of the great plague, 1349, bought a piece of ground without the bar of West Smithfield, which he inclosed and had consecrated for the burial of the dead, and where, in that year alone, more than 50,000 bodies are said to have been interred. It was thereupon called the New Church-Hawe, and a chapel was built, wherein, about the year 1360, Sir Walter de Manny intended to found a college for a warden or dean and twelve secular priests; but in the next year that design was altered, when Michael de Northburgh, bishop of London, joined with him in the building and endowing a priory in this place for double the number of Carthusian monks, which was to be called "The Salutation of the Mother of God," and the foundation appears to have been finished about 1370. The gross revenue of this house at its surrender to King Henry VIII., June 10, 1535, amounted to 736*l.* 2*s.* 7*d.*, its clear income to 642*l.* 0*s.* 4½*d.* per annum. Bearcroft, in his 'Historical Account,' says the site of this house was first granted June 12, 1542, to John Bridges and Thomas Hale, for their joint lives; and April 14, 1555, to Sir Edward North, who was made a baron, 1st Marquess: his son, Roger Lord North, sold it May 31, 1565, to the duke of Norfolk, for 2500*l.*, whose son, Thomas Howard, earl of Suffolk, sold it in the 9th Jac. I., to Thomas Sutton, Esq., for 13,000*l.*, who founded upon it, and largely endowed, a most magnificent hospital, consisting of a master, preacher, a head schoolmaster, a second master, with forty-four boys and eighty decayed gentlemen, who have been soldiers or merchants, besides a physician, surgeons, registrar, and other officers and servants of the house. Besides the scholars upon the foundation, whose number is now limited to forty-two, the masters are allowed to receive certain others, whose number fluctuates from one to two hundred. The Charter-House is considered one of the first schools of the metropolis. Among the eminent persons who have received their education there, may be enumerated Dr. Isaac Barrow, the mathematician; Addison; Steele; Dr. Benson, bishop of Gloucester; Sir William Blackstone; the Rev. Dr. Charles Burney; and the late Sir Henry Havelock.

The Charter-House, no doubt, derives its name from a corruption of *chartreux*, a monastery of Carthusians. The persecution of certain monks of this house forms a striking feature in the history of the Reformation of the time of Henry VIII.

(See Dugdale's *Monasticon*, new edit., vol. vi., p. 6; Tanner's *Notit. Monast.*, edit. Nasmith, *Midd.* viii., 3; Bearcroft's *Hist. Account of Thomas Sutton, Esq.*, 8vo, Lond., 1737.)

CHARTER-PARTY. [SHIPS.]

CHARTISTS, the name given to a political party in this country, who propose extensive alterations in the representative system, as the most direct means of attaining social improvement, and whose views are developed in a document called the "People's Charter." The principal points of this proposed charter are, universal suffrage, vote by ballot, annual parliaments, the division of the country into equal electoral districts, the abolition of property qualification in members and paying them for their services. The principles of the charter and the means of carrying them into effect have also been embodied in the form of a bill. It was prepared in 1838, by six members of the House of Commons and six members of the London Working Men's Association; and the following are the most important of its enactments: I. The preparers of the Bill allege the low state of public feeling as an apology for not admitting women to the franchise, and it is therefore only provided that every male inhabitant be entitled to vote for the election of a member of the Commons' House of Parliament, subject however to the following conditions: 1. That he be a native of these realms, or a foreigner who has lived in this country upwards of two years, and has been naturalised. 2. That he be twenty-one years of age. 3. That he be not proved insane when the lists of voters are revised. 4. That he be not convicted of felony within six months from and after the passing of this Act. 5. That his electoral rights be not suspended for bribery at elections, or for personation, or for forgery of election certificates, according to the penalties of this Act. II. That the United Kingdom be divided into 300 electoral districts, so as to give uniform constituencies of about 20,000 voters each. III. That the votes be taken by ballot. IV. That a new parliament be elected annually; that the elections take place on the same day in all the districts; and that electors vote only for the representative of the district in which they are registered. V. That no other qualification be required for members than the choice of the electors. VI. That every member be paid 500*l.* a year out of the public treasury for

his legislative services; and that a register be kept of the daily attendance of each member.

There is nothing new in the principles or details of the People's Charter. They have either separately, or some one or other of them in conjunction, been a prominent subject of discussion at various intervals within the last eighty years. In 1780 the Duke of Richmond introduced a bill into the House of Lords for annual parliaments and universal suffrage. In the same year the electors of Westminster appointed a committee to take into consideration the election of members of the House of Commons, and in their report they recommended the identical points which now constitute the main features of what is called the People's Charter. The Society of the Friends of the People, established in 1792, three years afterwards published a declaration which recommended a very large extension of the suffrage. In seasons of national distress, the amendment of the representative system has always been warmly taken up by the people of this country.

In 1831 the wishes of a large mass of the middle classes were realised by the passing of the Reform Act. A season of political repose, and, as it happened also, of commercial prosperity, followed the excitement which preceded the passing of that measure. A victory had been gained, and the people waited for the benefits which they were to derive from it. In the next period of distress which arose, the amended state of the representative system and the advantages which it had brought were narrowly scanned; and the consequence was, the gradual formation of a party who were dissatisfied with its arrangements, and sought to attain the ends of political and social good by a more extensive change. This is briefly the origin of Chartism and of the People's Charter. The middle classes were, however, well satisfied on the whole with the overthrow of the rotten boroughs and the enfranchisement of the large towns, and therefore the Chartists stood alone, and began to regard them with a feeling of hostility. Chartists were sometimes found, as in all other parties, ready to assist the party which differed most widely from them, with the object of thwarting the political objects which the middle classes had at heart. In 1838 they had become a large party and embraced a great number of the working classes employed otherwise than in agriculture. The number of signatures attached to the petition presented at the commencement of the session of 1839 in favour of the People's Charter was upwards of one million and a quarter. Unfortunately the idea began to be entertained amongst a certain class of the Chartists that physical force might be justifiably resorted to if necessary for obtaining political changes; and the party became divided into the Physical Force Chartists and the Moral Force Chartists. The former became implicated in disturbances which took place at various times in several parts of the country; and many persons of this class never having had correct views respecting the wages of labour, it appeared as if they had adopted the cry of "a fair day's wages for a fair day's work" as an additional point of the People's Charter. The disturbances in 1842 in the midland and northern counties were to some extent encouraged by the less intelligent of the Physical Force Chartists. At the close of 1841 however an attempt was made to combine the middle classes with the Chartists in their attempt to obtain an extension of the suffrage. Early in 1842 a Complete Suffrage Union was formed at Birmingham: and in April of the same year a conference, consisting of eighty-seven delegates, was assembled at Birmingham, which sat for four days; three of which were spent in agreeing upon a basis of union between the middle and working classes, and the last day in adopting plans of practical organisation. The six points of the People's Charter were adopted by the conference, and the details were left for settlement to a future conference. It was resolved also at this conference to establish a National Complete Suffrage Union. The proposed National Conference commenced its meetings in December, 1842, and was attended by 374 delegates. Here a rupture took place between the Chartists and the Complete Suffrage party, and the latter were outvoted on the question of adopting the People's Charter instead of the Complete Suffrage Bill. The minority however proceeded to act upon their views as developed in the Complete Suffrage Bill. This bill does not contain any disqualifying clauses. In other respects it differs from the People's Charter only in matters of detail. The Chartists and the Complete Suffragists are only nominally distinct parties; and the former are now almost extinct as a party, having merged into the Complete Suffrage party, which however has some unimportant subdivisions.

CHASE, that part of a gun which is between the ring near the trunnions, and the astragal mouldings near the muzzle.

CHASING OF METALS. The process termed chasing, or chasing, as applied to working in metals, so far resembles a kind of stamping as to admit of the two processes being described here together.

Metallic goods are generally made in one of three ways—by casting in moulds, by forging or turning in masses, or by pressing or stamping out of thin sheets. The last of these three has been greatly developed at Birmingham within the last few years. Either the entire article receives its form from the sheet by stamping, or, when roughly formed, it receives an ornamental device by the action of fine punches. For the latter variety of work, steel blocks, punches, or bosses, are provided, each one presenting at the end a definite form, such as curved, angular, square, &c.; and these are fixed or held with the finished end

uppermost. The article to be ornamented, which is always of a thin hollow kind, is placed face uppermost on the punch; a pattern or design is drawn on the face of the article, and the adjustment is so made that the punch beneath shall follow the course of the lines in the device. A fine hammer is then employed to strike the piece of thin metal; the effect of which is, that the metal is forced upwards in a fine burr or protuberance at every place where there is a punch beneath it. By shifting the piece of metal so that different parts of its lower surface may in succession be brought over the punch, and by changing the form of the punch when necessary, a protuberant design or pattern in relief is formed on the article of metal. In the finer kinds of metal work greater sharpness, relief, and finish are then given to the design by going over it with very sharp-cutting tools; and it is upon this last part of the process, and which is that technically known as chasing or enchasing, that the artistic character of the work largely depends.

But a more extensive kind of manufacture is that in which the article receives its form by being stamped or pressed from a plain piece of sheet metal. The hammer, the swage, the roller, the stamp, and the lathe are all employed to effect this, according to the thickness of the metal and the nature of the article to be made from it. When vessels and hollow articles are fashioned out of thin sheet-metal by the hammer, it constitutes *brazing*: the metal is rested upon bosses or steel supports of different kinds, and hammered on the upper surface till it assumes the requisite curvatures. The swage is a peculiar kind of gauge or pattern which gives the requisite form to the sheet metal by pressure rather than by percussion. Let us suppose (as a familiar mode of illustrating its action) that a pair of scissors has the two blades so curved that the convexity of the one may fit into or correspond with the concavity of the other; if these blades were nearly closed, and a thin piece of metal were drawn between them, it would be forced into a curved form similar to that presented by the blades. The arrangement of the different parts of the swage is so managed as to lead to some such result as that here indicated. The beadings and hollows on the edges of dish-covers and similar articles are produced by means of swages.

Many articles, such as large plain hollow vessels, are brought into form mainly by rollers. Tinsmiths often employ three rollers to bring their tin to the proper form for tubes and cylindrical vessels. There are two rollers placed nearly in contact, and in the same horizontal level; another is placed above them, equidistant from both; all are capable of revolving, and if a piece of tinned iron be drawn between them, it will be forced to conform to the size and shape of the cavity existing between the upper and the lower rollers: by varying the sizes and mutual distances of the rollers, different curvatures of the tin may be produced.

The lathe is employed in rather a singular way, in the production of various kinds of articles from thin sheet-metal, principally from soft white yielding alloys of tin and other metals. A flat circular disc of metal can by this means be brought to the shape of a cylindrical box, a cup, a hemisphere, or any one among numerous fanciful forms. The disc is attached to a lathe provided with a boss or block of the required shape, and a blunt tool is pressed against it while revolving; the soft and ductile metal yields to the pressure and conforms to the shape of the boss against which it is placed. By little and little the workman effects the transformation of the flat piece of metal to a shape which it could not assume unless it were soft and ductile. Teapots and other articles of Britannia metal are largely produced by this process, which is called "spinning."

The most important however of these modes of working sheet-metal is by stamping. In this process the thin metal is suddenly and very forcibly compressed between two steel dies or stamps, each of which is engraved with a pattern or device. One die is fixed on a stand with its face uppermost, while the other is fixed face downwards to the lower end of a heavy hammer or weight. The thin piece of metal is placed on the lower die; the hammer with the upper die is raised by a rope and pulley to a considerable height, and on this being allowed suddenly to fall, the upper die forcibly compresses the thin piece of metal which lies between it and the lower, compelling it to assume alternate convexities and concavities according to the pattern. Each die is an exact counterpart or reverse of the other, like the two halves of a swage, so that the metal cannot conform to the convexity of the one without falling into the concavity of the other; and it is by this double action that the result is produced. Spoons, forks, and trinkets in numberless variety are produced by stamping between two dies modified in various ways according to the particular object in view.

This mode of stamping requires as many dies as there are different patterns. The late Dr. Ure, in illustration of the heavy stock which the manufacturers at Birmingham are thus forced to keep by them, and of a difference in this respect between them and the French manufacturers, remarked: "M. Parquin, the greatest manufacturer of plated goods in Paris (or France, for this business is monopolised by the capital), who makes to the value of 700,000 francs per annum, out of the 1,500,000 which he says is the whole internal consumption of the kingdom, states that the internal consumption of the United Kingdom amounts to 30,000,000, or twenty times that of France. He adds that our common laminated copper costs 26 sous the pound, while theirs costs 34. Their plated goods are fashioned not in general with

stamps, but by the pressure of tools upon wood moulds in the turning-lathe, which is a great economy of capital to the manufacturer." This "pressure of tools upon wood moulds in the turning-lathe" corresponds with one of the processes above described, namely, the "spinning." It is believed that four of the establishments at Birmingham keep in stock more than a quarter of a million of different die-moulds for stamping the almost innumerable articles now made of thin brass, &c., in that busy centre of the metal trades.

For different applications of the above processes to manufactures, see *BUTTON*, and *COINING*; for the mode of making the dies, *DIE-SINKING*; and for stamping in connection with electro-gilding and silvering, *ELECTRO-METALLURGY*.

CHÂTELET, or **CHASTELET**, properly a little fortress. This name was afterwards given to certain courts of justice, formerly established in several cities of France, as at Orléans, Montpellier, &c. Le Grand Châtelet, at Paris, was the place where the presidial and ordinary court of justice of the provost of Paris was held. Le Petit Châtelet, at Paris, answered to its proper name; it was an ancient fort, serving as a prison. (Furetière, *Diction. Universelle*, 'Châtelet.')

CHATELS (*Catalla*). This term comprehends all property, moveable or immoveable, which is not freehold. Those chattels are called chattels real which, in the language of the earlier law writers, savour of the reality; that is, relate to, or are interests in land. Chattels personal are moveable goods, as horses, plate, money, &c. A lease is a chattel real. Chattels of each description pass to the personal representatives of the deceased proprietor, and are comprehended under the general term "personal property." The laws which govern this description of property are now, from the growth of the mercantile system and the change of manners, equal in importance with those relating to real estate; but under the feudal system, chattels (including even terms for years) were considered of small importance in a legal point of view; and, indeed, prior to the reign of Henry VI., were rarely mentioned in the law treatises and reports of the day. (Reeve's 'Hist. Eng. Law,' 369.) Many articles of property, intrinsically chattels, from their intimate connection with other property of a freehold nature, and being necessary to its enjoyment, descend therewith to the heir, and are not treated as chattels. Thus, for instance, the muniments of title to an estate of inheritance, growing trees and grass, deer in a park, and such fixtures as cannot be removed from the freehold without injury to it, are not chattels, because they pass to the heir. In the hands of a person however who has a limited interest in such things, they become his chattels, and pass to his executor. Chattels, except so far as they may be impressed with the nature of heir-looms, cannot be entailed, but they may be limited to trustees so as to vest in successive owners for life, and in unborn persons in fee, precisely as an estate-tail. They do not go in succession to a corporation sole, except only in the cases of the king and the chamberlain of the city of London. (Co. Litt.; Blackst., *Comm.*, Mr. Kerr's ed., vol. ii., pp. 393, 406, 438.)

CHAUCI, a nation of ancient Germany, who lived north-east of the Frisii, along the coast of the North Sea, on both banks of the Visurgis (Weser), and as far as the Albis, or Elbe. To the south they bordered upon the Catti. Their territories pretty nearly corresponded to the present Hanover and Oldenburg. Tacitus ('Germania,' 35) says that their country was extensive and thickly inhabited, and that they were a people distinguished among the Germans for their love of justice and of peace; powerful and yet unambitious, they did not provoke war, but were always ready to resist aggression. They were subdued by Tiberius, and continued for some time friends to Rome, furnishing auxiliaries to Germanicus in the war against the Cherusci. ('Annal.,' i. 60, ii. 17.) They were celebrated as navigators and pirates; and when under Claudius, they were driven by oppression into rebellion, the Chauci, under Gannascus, a chief of the Batavian tribe of the Cannine-fates, ravaged the coast of Gaul, and crossed the Rhine to make incursions into the Roman province of Germania Inferior; but they were defeated by Corbulo, who, however, failed in subjugating them, and they continued independent of Rome. ('Annal.,' xi. 18.) They afterwards joined in the revolt of the Batavian chief Civilis. ('Histor.,' iv. 79, v. 19.) The Chauci are last mentioned under the reign of Didius Julianus, when they belonged to the confederacy of the Saxons, and are said to have extended their territories to the banks of the Rhine.

CHECK, a species of checkered cloth, in which coloured lines or stripes cross each other rectangularly, like a chess-board. This manner of beautifying webs is probably very ancient. Many of the figures in Rosellini's Egyptian work are dressed in checkered cloths. Bishop Anselm's book concerning 'Virginity,' written about the year 680, when the art of weaving in this country was probably in a comparatively rude state, contains a distinct indication that checkered robes were then in fashion: "It is not a web of one uniform colour and texture, without any variety of figures that pleaseth the eye and appeareth beautiful, but one that is woven by shuttles, filled with threads of purple, and many other colours flying from side to side, and forming a variety of figures and images in different compartments with admirable art." These compartments, defined and bounded by coloured threads, may reasonably be regarded as checks; nevertheless, it is well to admit that other kinds of woven material would sufficiently answer to Anselm's description.

As manufactured at the present day, checks are sometimes pro

duced not by differently coloured threads, but by threads of different fineness and quality. Thus, if the chain, warp, or longitudinal yarns of the web be composed of alternate parcels of white cotton and woollen threads, and the transverse yarns, or the woof, be also composed of such alternate parcels, we shall have a check very distinctly brought forth without any distinction of colour, properly so called.

Cotton handkerchiefs checked of various colours have been manufactured in India probably from time immemorial under the name of *pullicates*. They were first imported into this country from Madras, whence they derived the name by which this style is still known in the trade,—there being a town of Pulicat or Pullicate a few miles north of Madras. The ground of these has usually a pale buff colour, and is

hand, and with a dexterous jerk causes one of the shuttles lodged in the separate cells at DD to move from one side of the loom to the other across the line of the warp, by means of the string which extends from that peg to the drivers or peckers (EE) seen at the end of the cells. The three shuttle-boxes here shown, are so constructed as to be made to slide up and down in a vertical plane, so that each box with its appropriate shuttle may at pleasure be brought on a level with the shuttle-race, or open shedding of the warp, and thus be thrown across. These three boxes are suspended by cords from the cross levers (GG), which turn upon centres, in the suspending bars marked BB, or the swords of the lay, being the levers which make it vibrate backwards and forwards in the act of weaving: A represents the cross-bar of wood on which the lay C oscillates upon iron gudgeons, or pins driven into each of its ends, and resting upon the upper rails of the loom, as shown in section. The under part of the lay is seen at C, and the upper part, called the lay-cap (H), is seized by the weaver's left hand in driving home each shute or shoot of weft. The two pieces of buffalo hide called the drivers or peckers (EE) are perforated, and traverse or slide horizontally upon smoothly polished iron rods. These pieces give the immediate impulsion to the shuttle. The weavers' twitch at the picking peg H must be sufficiently smart to communicate adequate velocity to the shuttle, so as to lodge it in the opposite box, and overcome its friction along the warp-race; on the other hand, he must avoid giving it too forcible a pull, which might do injury to its point, or throw it out of the shed. The pin H is made to slide freely from right to left upon the upper bar of the lay, and thus give such motion to the levers (GG) as may bring the proper box opposite to the shuttle-driver.

As diversity of woof renders diversity of shuttles necessary, it becomes expedient to shift them rapidly, otherwise the operation would be much impeded. The above plan is not the one originally employed, but is in many respects better. The pin (H) being fixed by friction only, so as to slide from right to left on the upper shell of the lay, the levers (GG) connected with it may be readily moved, being within reach of the weaver's hand, as he works the lay. The driver, if drawn forward, would present an obstruction to the shifting of the boxes, but this may be easily avoided by an experienced operative.

Mr. Robert Kay, of Bury, son of the most ingenious but persecuted inventor of the fly-shuttle, invented the above-described drop-box, for making checks; by means of which, as we see, the weaver could at pleasure use any one of three shuttles without rising from his seat, each shuttle containing a differently coloured weft.

The relation which this production of checks bears to other departments of textile manufacture will be further illustrated under WEAVING.

CHEESE. [CASEIN.]

CHEESE. The milk of animals consists of three distinct substances, which are separated from one another by a slight change, which begins as soon as it is exposed to the air. The oily part rises to the surface by its less specific gravity, and when it is collected into a solid mass by agitation it forms butter; the curd, coagulated by the action of any acid, and pressed, becomes cheese; and the fluid which remains is the serum or whey.

In the making of cheese there are certain general principles which are essential, but slight variations in the process produce cheeses of very different qualities; and, although a very important circumstance is the nature of the pasture on which the cows are fed, yet much depends on the mode in which in its different stages the fabrication is managed; and hence the great superiority of the cheeses of particular districts or dairies over those of others, without any apparent differ-

woven with the nankin yellow cotton. Checks in this country are mostly manufactured for the coarser purposes of seamen's shirts, aprons, and bedgowns of females in the lower ranks of life. The quantity required is so great as to make it a very important branch of business, and to render every mechanism which facilitates the fabrication an object of consequence. Blackburn in England, and Kirkaldy in Scotland, are the two chief seats of the check trade; the former in cotton, and the latter, till of late years, chiefly in linen yarns.

For the decussation or weaving of woof yarns of different kinds or colours in one web, different shuttles must be in readiness for alternate use. The mode in which this is effected is shown by the figure.

Here we see the picking peg (F), which the weaver seizes in his right

hand, and with a dexterous jerk causes one of the shuttles lodged in the separate cells at DD to move from one side of the loom to the other across the line of the warp, by means of the string which extends from that peg to the drivers or peckers (EE) seen at the end of the cells. The three shuttle-boxes here shown, are so constructed as to be made to slide up and down in a vertical plane, so that each box with its appropriate shuttle may at pleasure be brought on a level with the shuttle-race, or open shedding of the warp, and thus be thrown across. These three boxes are suspended by cords from the cross levers (GG), which turn upon centres, in the suspending bars marked BB, or the swords of the lay, being the levers which make it vibrate backwards and forwards in the act of weaving: A represents the cross-bar of wood on which the lay C oscillates upon iron gudgeons, or pins driven into each of its ends, and resting upon the upper rails of the loom, as shown in section. The under part of the lay is seen at C, and the upper part, called the lay-cap (H), is seized by the weaver's left hand in driving home each shute or shoot of weft. The two pieces of buffalo hide called the drivers or peckers (EE) are perforated, and traverse or slide horizontally upon smoothly polished iron rods. These pieces give the immediate impulsion to the shuttle. The weavers' twitch at the picking peg H must be sufficiently smart to communicate adequate velocity to the shuttle, so as to lodge it in the opposite box, and overcome its friction along the warp-race; on the other hand, he must avoid giving it too forcible a pull, which might do injury to its point, or throw it out of the shed. The pin H is made to slide freely from right to left upon the upper bar of the lay, and thus give such motion to the levers (GG) as may bring the proper box opposite to the shuttle-driver.

ence in the pasture. By skill and great attention excellent cheeses are made in places where the pastures are not considered so well adapted to produce milk of a proper quality; and in those countries where the cows are chiefly kept tied up in stalls, and are fed with a variety of natural and artificial grasses, roots, and vegetables, superior cheese is often made.

The first process in making cheese is to separate the curd from the whey: this may be done by allowing the milk to become sour; but the cheese is then inferior in quality, and it is difficult to stop the acid fermentation, and prevent its running into the putrefactive. Various substances added to milk will soon separate the curd from the whey. All acids curdle milk. Muriatic acid is used with success for this purpose in Holland. Some vegetables contain acids which readily coagulate milk, such as the juice of the fig-tree, and the flowers of the *Galium verum*, or yellow lady's bed-straw, hence called *cheese rennet*. Where better rennet cannot be procured, they may be substituted for the most natural curdler of milk, which is the gastric juice of the stomach of a sucking calf. This juice rapidly coagulates the milk as the calf sucks; and the only difficulty is in collecting and keeping it from putrefaction, which begins from the instant the stomach is taken from the calf. The preparation of the *rennet*, as it is called, is a most important part of the process of cheese-making. The following may be considered as the simplest, and perhaps the best: As soon as a sucking calf is killed, the stomach should be taken out, and if the calf has sucked lately, it is all the better. The outer skin should be well scraped, and all fat and useless membranes carefully removed. It is only the inner coat which must be preserved. The coagulated milk should be taken out and examined, and any substance besides curd found in it should be carefully removed. The serum left in it should be pressed out with a cloth. It should then be replaced in the stomach with a large quantity of the best salt. Some add a little alum and sal prunella; others put various herbs and spices, with the view of giving the cheese a peculiar flavour, but the plain simple salting is sufficient. The skins or vells, as they are called, are then put into a pan and covered with a saturated solution of salt, in which they are soaked for some hours; but there must be no more liquor than will well moisten the vells. They are afterwards hung up to dry, a piece of flat wood being put crosswise into each to stretch them out. They should be perfectly dried, and look like parchment. In this state they may be kept in a dry place for any length of time, and are always ready for use. In some places, at the time of making cheese, a piece of a vell is cut off and soaked for some hours in water or whey, and the whole is added to the warm milk. In other places, pieces of vell are put into a linen bag and soaked in warm water, until the water has acquired sufficient strength, which is proved by trying a portion of it in warm milk. The method employed in Switzerland is as follows: A dry vell is taken and examined; it is scraped with a knife, and where any veins or pieces of tough membrane appear, they are removed. The whole surface is examined and washed carefully, if any dust or dirt has adhered to it; but otherwise it is only wiped with a cloth. A handful of salt is then put into it, and the edges of the vell are folded over and secured with a wooden skewer stuck through it. In this state it forms a ball of about three inches diameter, and is laid to soak twenty-four hours in a dish containing about a quart of clear whey, which has been boiled, and all the curd taken out. The next day the vell is well squeezed, and put into fresh whey; the first infusion being put into a proper vessel, the second is afterwards mixed with it, and bottled for use. Half a pint of this liquor, of a proper strength, is sufficient to curdle forty gallons of milk. Experience alone enables the dairyman to judge of the strength of his rennet; for this purpose he takes in a

flat ladle some milk which has been heated to about 95° of Fahrenheit, and adds a small measure of rennet; by the rapidity with which it curdles, and the form of the flakes produced, he knows its exact strength and puts more or less into the caldron in which the milk is heated for curdling. A simple instrument might be easily invented, by which the exact degree of strength might be ascertained, and a rule given to guide the less experienced; but as long as a man feels a superiority acquired by experience alone, he is not likely to encourage any contrivance which would place others on a level with himself. From this cause even the thermometer has not been introduced generally into any great dairy, nor have any certain rules been given to ascertain the exact heat required in the milk, when the rennet is added, to form the best curd.

There are different kinds of cheese, according to the mode of preparing it: soft and rich cheeses are not intended to be kept long; hard and dry cheeses are adapted to be kept and stored for provisions. Of the first kind are all cream cheeses, and those soft cheeses called Bath cheeses and Yorkshire cheeses, which are sold as soon as made, and if kept too long become soft and putrid. Stilton and Gruyère cheeses are intermediate; Parmesan, Dutch, Cheshire, Gloucestershire, and similar cheeses, are intended for longer keeping. The poorer the cheese is the longer it will keep; and all cheese that is well cleared from whey and sufficiently salted will keep for years. The small Dutch cheeses called Edam cheeses are admirably adapted for keeping, and form an important article in the victualling of ships.

The Gruyère and Parmesan cheeses only differ in the nature of the milk, and in the degree of heat given to the curd in different parts of the process. Gruyère cheese is entirely made from new milk, and Parmesan from skimmed milk. In the first nothing is added to give flavour; in the latter saffron gives both colour and flavour: the process in both is exactly similar. A large caldron in the shape of a bell, capable of holding from 60 to 120 gallons of milk, hangs from an iron crane over a hearth where a wood fire is made. The milk, having been strained, is put into this caldron, and heated to nearly blood-heat (95° to 100°). It is then turned off the fire, and some rennet, prepared as stated above, is intimately mixed with the warm milk by stirring it with the hand, in which is held a flat wooden skimming-dish, which is turned round in the milk while the hand and arm stir it. A cloth is then laid over the caldron, and in half an hour, more or less, the coagulum is formed. This is ascertained by pressing the skimming-dish on the surface, when the whey will appear on the part pressed. If it is longer than an hour in coagulating, the milk has been too cool or the rennet not strong enough. The weather has a great influence on the process of the dairy, and there is much yet to be learned by accurate observations with meteorological instruments, especially electrometers. When the curd is properly formed, it is cut horizontally in thin slices by the same skimming-ladle. Each slice, as it is taken off, is poured along the side of the caldron which is nearest to the operator; by this means every portion of the curd rises successively to the surface, and is sliced thin. The whole is then well stirred, and the caldron is replaced over the fire. A long staff, with a small knob of hard wood at the end, and which has smaller cross pieces or sticks passed through holes in it at right angles to each other near the end, is now used to stir and break the curd, and the heat is raised to about 135°, which is as hot as the arm can well bear, even when used to it. The caldron is again swung off the fire, and the curd is stirred with the staff, which is moved round with a regular rotatory motion, the knob running along the angle formed with the side by the bottom of the caldron, which is in the form of a bowl. After stirring in this manner nearly an hour, the curd is found divided into small dice about the size of a pea, which feel elastic and rather tough under the finger. Experience alone can teach the exact feel they should have. The whey, of which a portion is removed occasionally, now floats at top, and the curd is collected in the bottom by giving a very rapid rotatory motion to the contents of the caldron by means of the staff. A cloth is now introduced into the bottom, and all the curd collected over it; it is raised by the four corners, and laid on an instrument like a small ladder, which is placed across the mouth of the caldron. The whey runs out through the cloth, which is a common cheese-cloth, woven with wide interstices; and the curd in the cloth is placed in a shape or hoop made of a slip of wood four inches and a half wide, the two ends of which lie over each other, so that the diameter can be increased or lessened. A cord fixed to one end of the hoop is passed with a loop over hooks on the outer surface of the other end, and prevents the ring from opening more than is required. The curd is pressed into this ring with the hands, and the ends of the cloth are folded over it. A round board, two inches thick, and strengthened by cross pieces nailed on it, is placed over the curd, and the press let down upon it.

The cheese-press is a simple long board or frame forming a lever, loaded at one end and moving in a frame at the other; it is lifted up by another lever connected with it, and let down on a strong stick, which stands with its end on the centre of the board last-mentioned. Thus the weight is easily removed or replaced. The hoop containing the cheese is placed on a similar board, and from it the table of the press slopes towards a wooden trough, which receives the whey as it runs out. In an hour after this, the curd is examined; the edges, which are pressed over the ring, are pared off, and the parings are put

on the centre of the cheese; a fresh cloth is substituted, and the whole cheese is turned. The ring, which opens readily by unhooking the cord, allows the cheese to come out, and is put on again and tightened. This is repeated two or three times in the day. In the evening, a small portion of finely powdered salt is rubbed on each side of the cheese, and it remains in the press till the next morning. It is now again rubbed with salt, and placed on a shelf with a loose board under it. The wooden ring remains on the cheese for two or three days, and is then taken off. This is the whole process.

During the next six or eight weeks, the cheeses are turned and wiped every day, and a small quantity of fine salt is sifted on the surface and rubbed in with the hand until it will take no more. The cheese-room is always very cool, and little light is admitted. A free circulation of air is essential. The cheeses are in perfection in about six months, and will keep two years. A quantity of elastic fluid is disengaged in the ripening, and forms those round eyes which are a peculiar feature in these cheeses. The smaller and rounder the eyes, the better the cheese is reckoned. They should contain a clear salt liquor, which is called the tears; when these dry up, the cheese loses its flavour. These particulars will give any one unacquainted with the dairy a tolerable notion of the process of cheese-making in general.

In Cheshire the making of cheese is carried on in great perfection, and the greatest pains are taken to extract every particle of whey. The dairy management is as follows: The cows are milked at night, and the milk is poured into tin pans on the floor of the milk-house. This milk is skimmed in the morning, and then poured into the large tub where the curd is "set." As the morning's milking proceeds, the pails full are brought one after another and poured into this tub. A pan of milk is warmed in a boiler in the dairy, and when sufficiently hot the cream just taken from the evening's milk is mixed with it, and the whole thus warmed is poured at last into the tub which thus contains the whole milk, cream and all, of both "meals." The colouring matter, "annatto," apparently about a gill, is added to the 100 or 120 gallons which may be then in the tub as the produce of 48 to 50 cows; a half handful of saltpetre is thrown in with the view of correcting the bitterness which is to be detected while the butter-cups are in full leaf; and the rennet, about a pint of brine in which two or three little bits of the prepared vells or "bag skins" have been steeped over night, is added to the milk, which is then left for an hour covered up till the curd has fully formed. It is then cut slowly with a wire curd breaker, and the curd sinking, the whey is baled out; the curd is collected and squeezed both by hand and by the direct pressure of a weight above a board placed upon it, and the last of the whey being removed it is lifted into one of the large Cheshire cheese vats pierced with holes for the further escape of fluid; the lower part being a wooden cylindrical vat, and the upper a tinned cylinder slipping into it as the curd on pressure sinks. After a certain pressure in this form, the curd is removed and cut and broken by hand, and from 1 to 2 lbs. of fine salt is scattered over it, and the whole rebroken and refilled into the vat, into which a cheese cloth has previously been placed. There it remains for the day, yielding somewhat to the pressure of its own weight. It is then put gradually under pressure, which on the second or third day amounts to nearly a ton weight upon each cheese.

Every day the cheese is turned and wrapped in fresh cloths, and on the seventh or eighth day of this treatment, or as soon as dry, it is removed to the loft and there, swathed around with strong girthing, placed on a bench. By-and-by it is laid, still swathed as before, on a layer of straw on the floor of the room, and there it lies till from ten weeks to four months old, when it is ready for sale.

This is pretty generally the history of a Cheshire cheese. In some dairies, in order to the perfect extraction of the whey, skewers are used to pierce it, being thrust repeatedly into it through the holes in the cheese vat, in order to the formation of drains for the liquid. The whey is heated in a boiler, and throws up a cream, called "fleetings," which is skimmed twice, the first yielding a very good butter, and the latter a substance used principally for feeding calves; the whey is afterwards given to the pigs. Excepting a portion of the cream from the milk used in the house, and that which thus comes from the whey, the Cheshire cheese is a whole-milk cheese, and as rich, therefore, as any that is made.

Gloucester and Somersetshire cheeses are similarly made, with this difference, that the curd is not so often broken or the cheese skewered, and a portion of the cream is generally abstracted to make butter. After the curd has been separated from the whey and is broken fine, a little warm water is sometimes poured over it for the purpose of washing out any remaining whey, or perhaps to dissolve any portion of butter which may have separated before the rennet had coagulated the milk; for although cream adds to the richness of cheese, butter tends to make it rancid. This practice is, however, both lazy and mischievous, inasmuch as it impoverishes the curd. Gloucester cheeses, too, are not so heavy as Cheshire, or as Cheddar and other Somerset cheeses.

Stilton cheese is made by adding the cream of the preceding evening's milk to the morning's milking. The cream should be intimately incorporated with the new milk; great attention should be paid to the temperature of both, and much of the quality of the cheese depends on this part of the process. To make this cheese in perfection, as

much depends on the management of the cheese after it is made as on the richness of the milk. Each dairy-woman has some peculiar method which she considers as the best; and it is certain that there is the greatest difference between cheeses made in contiguous dairies. The rennet should be very pure and sweet. When the milk is coagulated, the whole curd is taken out, drained on a sieve, and very moderately pressed. It is then put into a shape in the form of a cylinder, eight or nine inches in diameter, the axis of which is longer than the diameter of the base. When it is sufficiently firm, a cloth or tape is wound round it to prevent its breaking, and it is set on a shelf. It is occasionally powdered with flour, and plunged into hot water. This hardens the outer coat and favours the internal fermentation, which ripens it. Stilton cheese is generally preferred when a green mould appears in its texture. To accelerate this, pieces of a mouldy cheese are sometimes inserted into holes made for the purpose by the scoop, called a *taster*, and wine or ale is poured over for the same purpose; but the best cheeses do not require this, and are in perfection when the inside becomes soft like butter, without any appearance of mouldiness. In making very rich cheeses the whey must be allowed to run off slowly, because, if it were forced rapidly, it might carry off a great portion of the fat of the cheese. This happens more or less in every mode of making cheese. To collect this superabundant butter, the whey is set in shallow pans, as is done with milk when butter is made; and an inferior kind of butter called *whey butter* is made from the cream or fat skimmed off. Keevil's cheese-making machine, which cuts by the slow revolution of a framework of wires through the curd, separates the whey so gradually that no buttery matter is carried off with it, and no whey butter can be formed.

Cheeses are frequently coloured, a practice which probably arose from the notion of making the cheese look richer; but now it deceives no one. Yet if some cheeses were not coloured, they would not be so marketable, owing to the association that subsists between the colour and the quality of the cheese. The substance used for colouring is most commonly *arnotto*. [ARNOTTO.] It is ground fine on a stone, and mixed with the milk at the time the rennet is put in. The juice of the orange carrot, and flower of the marygold, are also used for this purpose. This last give a more natural tint than the *arnotto*, which is too red. Cheddar cheese made in Somersetshire, which is highly prized, Stilton, Derby, and some other cheeses, are never coloured; Cheshire slightly; but some dairies in Gloucester and North Wiltshire colour deeply. Foreign cheeses are only coloured very slightly, if at all; the Dutch cheeses are made in a very similar manner to the Gloucester cheeses, but the milk is generally curdled by means of muriatic acid or spirits of salt: and great care is taken to prevent fermentation, and to extract the whole of the whey. For this purpose the curd is repeatedly broken and pressed; and before it is made up into the round shape in which it is usually sold, the broken curd is well soaked in a strong solution of common salt in water. This diffuses the salt throughout the whole mass, and effectually checks fermentation. When the cheeses are finally pressed, all the whey which may remain is washed out with the brine; salt is likewise rubbed over the outside, and they are set to dry on shelves in a cool place. The flavour of the cheese is perhaps impaired by the stoppage of the fermentation; but it never heaves, and it acquires the valuable quality of keeping well even in warm climates. From the place where this cheese is commonly made, it is known by the name of Edam cheese. A finer cheese is made at Gouda and other places, by imitating the process in making Gruyère cheese; but this cheese is always full of small cavities, and will not keep so long as the Edam. The cheese most commonly met with in Holland is a large kind of skim-milk cheese, which is made very like Cheshire cheese. It grows hard and dry, and has not much flavour. To supply this defect, cummin seeds are mixed with the curd, which those who are accustomed to it consider a great improvement. On the whole it is a better cheese than our Suffolk skim-milk cheese, and forms an important part of the provisions usually stored for a Dutch family. In France the Roquefort cheese is compared to our Stilton, but is much inferior, although a good cheese. The little cheeses made from cream and folded in paper, called Neufchâtel cheeses are imported from France as a delicacy. They can be easily imitated, being nothing more than cream thickened by heat, and pressed in a small mould. They undergo a rapid change, first becoming sour and then mellow, in which state they must be eaten.

A small cheese, much relished by all ranks, is made in the north of Germany in the simplest manner. It is usually made from milk from which the cream has been taken off to make butter,—although the entire milk is much better. This is curdled by being placed near a fire. When it has become somewhat sour, it is put into a linen bag, and all the whey well pressed out. When it is tolerably solid, it is broken by the hand in a tub, and made very fine. It remains in this state several days, until a considerable alteration takes place, and the putrid fermentation begins, as is readily perceived by the odour. It is then taken in small portions, and formed into flattened balls three or four inches in diameter, by beating them in the hands. These balls are ranged on a board, and set to dry. A portion of caraway seed is generally mixed with the curd. In a few days the mellowing goes on, and the centre becomes very soft. In this state it is a great dainty for those who disregard a pungent and fetid smell. They are some-

times placed in the smoke of a chimney where the putrid fermentation is checked and confined to the centre by the pyroligneous acid arising from a wood fire. They remain in the chimney a considerable time; and when they are used the outer part is peeled off like the rind of an apple. A whole cheese is a mere mouthful. It gives a relish to the sour black rye bread generally eaten by the lower orders.

The green Swiss cheese, commonly called *Schabzieger*, which is made in the canton of Glarus, and is by many persons highly esteemed, is made somewhat in the same manner. The curd is pressed in boxes with holes to let the whey run out; and when a considerable quantity has been collected and putrefaction begins, it is worked into a paste with a large proportion of a certain dried herb reduced to powder. This herb, called in the country dialect *Zieger kraut* (curd-herb), is the *Melilotus officinalis*, which is very common in most countries, and has a peculiar aromatic flavour in the mountains of Switzerland. The paste thus produced is pressed into moulds of the shape of a common flower-pot, and the putrefaction being stopped by the aromatic herb, it dries into a solid mass, which keeps unchanged for any length of time. When used it is rasped or scraped, and the powder mixed with fresh butter is spread upon bread. It is either much relished or much disliked, like all those substances which have a peculiar taste and smell.

A species of cheese or rather hard curd is made in the mountains of Switzerland from the whey which has run from the common cheese made of the whole milk. It is called *serré*. When the Gruyère or the Jura cheese, which is often sold by the same name, has been put under the press, a quantity of fermented whey, about two or three gallons, is poured into the caldron with the new whey, and the whole is heated over the fire till a thick scum rises. This is taken off when the whey is nearly boiling, and put into a square box with holes in it; the whey which remained mixed with the curd, and which is now very blue, is allowed to run out, and a small pressure assists it. When a cheese of sixty pounds has been made, the *serré* will often weigh twenty pounds. This mass of curd readily dries on the shelf, and becomes hard. It has little flavour, but it serves the people on the mountains for bread. They cut slices of it, spread some butter over, and put a thin slice of cheese upon this: washed down with a cup of fresh or of fermented whey, it forms the chief food of the mountain herdsmen. The only luxury indulged in is an occasional glass of *kirsch-wasser*, a spirit distilled from cherries, or of gentian brandy, from the root of the *Gentiana officinalis*.

When a cheese which has been much salted and kept very dry is washed several times in soft water, and then laid in a cloth moistened with wine or vinegar, it gradually loses its saltiness, and from being hard and dry, becomes soft and mellow, provided it be a rich cheese. This simple method of improving cheese is worth knowing. It is generally practised in Switzerland, where cheeses are kept stored for many years, and if they were not very salt and dry they would soon be the prey of worms and mites. A dry Stilton cheese may thus be much improved.

CHELERYTHRINE. [CHELIDONINE.]

CHELIDONIC ACID ($C_{14}H_8O_{12} + 2aq.$) occurs in the same plant as CHELIDONINE, in combination with that and other bases, principally, however, with lime. The lime salt may be obtained from the juice pressed from the fresh plant, best gathered when in full flower. This liquid is boiled, filtered, acidified with nitric acid, and solution of nitrate of lead added so long as a precipitate falls, care being taken not to add excess of nitrate. The washed precipitate still retaining lime is decomposed by passing sulphuretted hydrogen for two or three days through water in which it is suspended; the solution, filtered, is then neutralised with chalk, decolourised with animal charcoal, and evaporated to the crystallising point.

With the *chelidonate of lime* thus produced, combinations of chelidonic acid with almost any of the bases can be conveniently prepared by double decomposition with their neutral and other salts. An interesting class of compounds is thus obtained, containing one, two, or three equivalents of metal in the place of one, two, or three equivalents of hydrogen.

It is not easy to isolate chelidonic acid from its salts. Perhaps the best method is to obtain it from its combination with ammonia, a salt produced by double decomposition of chelidonate of lime and carbonate of ammonia. To a concentrated solution of this compound, twice its volume of strong hydrochloric acid is added. The whole usually sets into a solid mass, from which the chelidonic acid may be finally obtained pure by repeated crystallisation from water.

This acid forms long colourless needles. In the air they slowly effloresce. Heated to 212° Fahr. they lose their two atoms of water of crystallisation, and at a higher temperature decompose. They are soluble to a certain extent in cold water, but very much so in boiling water. They are also dissolved by alcohol.

Chelidonic acid dissolves in concentrated sulphuric acid, without alteration, unless heat is applied, when decomposition quickly occurs. Strong nitric acid acts very slowly upon it; slightly diluted, nitrous fumes are evolved, and an acid produced that has not yet been examined; it is not oxalic acid.

Chelidonic acid dissolves iron or zinc, with disengagement of hydrogen gas.

CHELIDONINE ($C_{40}H_{19}N_3O_6$?). An alkaloid found in the common

celandine (*Chelidonium majus*, nat. ord. *Papaveraceæ*). Probst recommends the following process for its preparation :

Exhaust the root with water acidified with sulphuric acid, precipitate the percolate by ammonia, digest the precipitate in alcohol, evaporate the solution to dryness, re-dissolve in water, and again precipitate with ammonia. A mixture of chelidonine and *chelerythrine* will thus be obtained ; the latter may be dissolved out with ether, and the former purified by dissolving in a small quantity of very dilute sulphuric acid, and adding about twice as much strong hydrochloric acid. Hydrochlorate of chelidonine then slowly precipitates in granular crystals, from which the alkaloid itself may be obtained by digestion in ammonia.

Crystallised from alcohol, chelidonine presents the appearance of little colourless tables, insoluble in water, soluble in ether. Heated it melts at 266° Fahr., and at a higher temperature decomposes.

Chelidonine is very soluble in acids, combining with them to form salts, which are for the most part crystalline. Their solutions are acid to test-paper, of a bitter taste and more or less decomposed by evaporation. They are said to be devoid of poisonous properties.

CHELIDOXANTHIN. A neutral non-nitrogenous matter found in the same plant as CHELIDONINE. It is precipitated by subacetate of lead from the expressed juice. If the lead precipitate be washed with water and decomposed in the usual way by sulphuretted hydrogen, it is obtained in confused groups of acicular crystals. It has a yellow colour and bitter taste, slightly soluble in cold water, much more so in hot water. Neither acids nor alkalies affect the solution.

CHELTENHAM, WATERS OF. In all the springs which emerge from the sandy vale of Cheltenham, the sulphate of soda or chloride of sodium predominates ; so that they belong to the class of saline waters. It is worthy of notice, that most of the saline springs of Great Britain take their rise in the new red sandstone formation. Mr. Gairdner remarks, however, that those of Cheltenham rise in a stratum of blue clay abounding in iron pyrites, which repose on the inferior oolite limestone ; a circumstance which, according to him, furnishes an explanation of the well-known fact, that these mineral waters are strongest when first opened, and gradually decrease in strength until it becomes necessary to sink new wells in order to obtain water of the requisite strength. The specific gravity of the water of four of the springs belonging to Thompson's Spa was observed to be diminished, and two to be increased, between 1817 and 1820, to such a degree as to excite the surprise of chemists. The number of springs at present is fourteen, each of which present some slight difference in the amount of the saline ingredients and their concomitants. The most important differences are owing to the presence of iron in some, occasionally accompanied with carbonic acid and sulphuretted hydrogen. Iodine in the proportion of about one grain to a gallon of the water exists in most of them, except the Pittville spring, in which however bromine is found in the proportion of one grain to six gallons of the water. Those in which no iron exists partake much of the nature of sea-water, and resemble it in effects when used internally ; while those in which it is present are of a chalybeate nature, and, especially when the quantity of carbonic acid is considerable, can be borne by persons who cannot tolerate the simple saline waters, and can likewise be used for a much longer time without inducing debility. It is sometimes advisable to change from one kind to another, according to the state or progress of the patient, all which points will be regulated by physicians on the spot.

The persons most benefited by the Cheltenham waters are those who, after a long residence in hot climates, are affected with diseased liver ; and also those who by indulgence in good living have weakened the stomach and intestines. The mucous accumulations which occur in the bowels of children subject to worms are best removed by a course of the pure saline waters, followed by the aerated chalybeate or the sulphureous chalybeate. Children subject to glandular enlargements derive much benefit from those waters which contain iodine along with iron.

CHEMICAL AFFINITY. This term is applied to denote the agent or power by which certain phenomena are produced when substances are brought into contact with each other. It is also used to signify the peculiar force or power, the presence of which in compound substances binds together or retains in combination the elementary bodies of which they are composed. Thus, when charcoal is ignited in contact with air, the light and heat produced are said to result from the exertion of chemical affinity between the charcoal and one of the constituents of the atmosphere,—namely, oxygen ; whilst the elements of the carbonic acid formed in this combustion are also regarded as being retained in combination by virtue of the permanent action of the same power—chemical affinity. This power is sometimes denominated the *chemical force*.

Chemical affinity may be distinguished from all the other powers of matter, except cohesion, by acting only between bodies which are either absolutely in contact or at insensible distances from each other. Thus, whilst gravity exerts its influence between particles of matter placed at inconceivably great distances, and light, heat, and electricity are capable of manifesting their effects through probably equally immeasurable spaces, there is not the slightest effect produced by placing a globule of potassium at the smallest perceptible distance from a drop of water, although these bodies are capable of displaying

an affinity of such intensity as to cause them to burst into flame when they are brought into actual contact.

From the force of cohesion, chemical affinity may also be distinguished by several marked peculiarities. Two pieces of glass ground perfectly flat and smooth, when placed upon each other and pressed together, cohere with such force as to require a weight of some scores of pounds to separate them ; indeed, it is stated that, if the pressure be great and long continued, the two pieces become so firmly united as to render their subsequent separation at the precise line of junction nearly impossible. The force holding the pieces of glass together,—cohesion, causes however not the slightest alteration in the properties or appearance of the bodies between which it is thus exerted, and if the two pieces of glass were of different colours they could still be individually distinguished in the compound mass. But the exertion of the chemical force is attended with very different results : when iron is exposed to air and moisture, it is, by the exertion of chemical affinity, gradually converted into a red-brown powder, well known as iron-rust, in which none of the peculiar properties of the metal or of the atmospheric oxygen are distinguishable. No one ignorant of the fact could imagine the bright, hard, and heavy metal iron to be present in the dull, friable, and comparatively light rust ; nay, even the most powerful microscope utterly fails to distinguish a particle of iron in the compound thus formed. Chemical affinity is therefore distinguished from cohesion by the complete change which it effects in the character and properties of the substances between which it is exerted. The force of cohesion may be overcome by mechanical power alone,—the hardest solids may by suitable mechanical means be reduced to impalpable powder ; but the separation of bodies united by the chemical force can very rarely be effected by mechanical agency alone ; no amount of grinding, fracture, or pulverisation can effect the slightest separation of the particles of iron and oxygen in the rust above mentioned.

The simplest cases of chemical affinity are those in which two elementary bodies unite into a binary compound, as when iron combines with oxygen to form oxide of iron. This is the result of what is termed *single affinity*, and this power may be exerted between two elementary or two compound bodies ; and also, though it occurs more rarely, between an elementary and a compound substance. For example, sulphur and copper, both elementary bodies, readily unite when heated ; sulphuric acid and oxide of copper, both compounds, combine with great readiness ; but no combination of sulphur and oxide of copper, or of sulphuric acid and copper, is at present known. There is then a greater disposition to combination between two elements or two compounds, than between an element and a compound. The rule is, however, by no means without exception ; for cyanogen, a compound body, combines with mercury, an elementary one, to form cyanuret of mercury.

It has been mentioned that, when bodies combine by chemical affinity, they undergo great change of properties. It might, however, be supposed that a compound would possess qualities intermediate between those of its constituents. This, however, is by no means the case ; nor, even though we may be well acquainted with the properties of the elements, can we at all tell, *a priori*, what kind of a compound they will form. Sulphur is yellow, copper is red, but the sulphuret of copper, resulting from their union, is black. Again, sulphuric acid has great affinity for water, and when diluted turns vegetable blues red. Potash has also great affinity for water, and renders vegetable blues green. The acid and potash are also both extremely acrid, and they have great affinity for each other ; but combine them by *single affinity*, and a salt, called sulphate of potash, is produced, which has very slight affinity for water, does not act upon any vegetable colours, and, instead of being acrid to the taste, like both its constituents, is merely bitter and saline. In this case of chemical affinity an almost total reversal of properties has occurred ; but there are cases in which it is far from being so complete, and in which one or both of the ingredients still exert some of their original powers : thus, the sulphate of potash, above alluded to, is capable of combining with an additional quantity of sulphuric acid. This salt, which is called bisulphate of potash, resembles both its constituents in having affinity for water, as is shown by crystallising in combination with it, and by being readily soluble in it ; and it resembles sulphuric acid in having a sour taste, and turning vegetable blues red.

We have stated a few examples of the changes produced in bodies by a combination effected by chemical affinity. The alterations, in many cases, are more striking and complete ; the properties of the substance formed by the combination being altogether different from those of the bodies from which it has originated. Sulphuret of copper, as already noticed, differs in colour from both its elements, yet it resembles both in being solid ; but there are numerous cases in which the form, colour, smell, taste, density, and other physical qualities, and the chemical properties of fusibility, volatility, solubility, and tendency to combination in the compound, bear no resemblance to its constituent parts.

Although, when speaking of the action which is induced by chemical affinity, chemists are frequently in the habit of stating merely that one substance has affinity for another, yet it is to be understood that the force with which bodies unite arises from mutual and equal affinity : thus, sulphuric acid and potash combine, not merely on account of the affinity of the acid for the alkali, but of the alkali

equally for the acid. Chemical affinity, then, is mutual and equal between those substances which combine by its power. Many different compounds may be formed by uniting one substance, an acid, for example, with various others, as with the alkalies, earths, and metallic oxides; these are called bases; and the force of affinity of any acid for any base differs in every instance. Now, this difference constitutes what has been termed *elective affinity*,—the existence of which is easily proved, and the results of its action are of the highest importance, both in a scientific point of view, and with regard to chemical agency as connected with the most common processes in the chemical arts and manufactures.

Nitric acid is capable of combining by *single affinity* with lime or with magnesia; and if some dilute nitric acid, containing 54 parts of real acid, be mixed with 28 parts of lime, the earth will be dissolved in the acid, and a neutral solution of nitrate of lime is obtained. A similar quantity of this acid forms a neutral solution of nitrate of magnesia by combining with 20 parts of that earth. Now, if we mix together 54 parts of nitric acid, 28 of lime, and 20 of magnesia, it might be supposed that the acid—which is of course incapable of dissolving the whole of both of the earths—would dissolve them in the proportions of 14 of lime and 10 of magnesia: it is found, however, that this is not the case, for the whole of the lime is dissolved and the magnesia entirely left.

It appears, then, a greater mutual affinity (an *elective affinity*) exists between nitric acid and lime, than between nitric acid and magnesia. There is another mode in which elective affinity acts, and in which it is employed in a vast number of chemical processes. It has been just stated that 54 parts of nitric acid combine with 20 of magnesia by single affinity. Now, if to the solution of nitrate of magnesia thus obtained we add 28 parts of lime, and boil the mixture, the lime separates the magnesia from the nitric acid; and being dissolved instead of it, we procure a solution of nitrate of lime, instead of nitrate of magnesia: this operation is termed *single decomposition*, and it is produced by single elective affinity. It is therefore evident, that this power may not only prevent one substance from combining with another when three are mixed, but supposing two to have been previously combined, it is capable of effecting a separation between them.

On the action of single elective affinity producing single decomposition, depends the process of preparing acetic acid from acetate of soda by means of sulphuric acid; and the production of ammoniacal gas by distilling a mixture of lime, sulphate of ammonia, and water.

To exhibit the degrees of elective affinity, tables were constructed by Geoffroy, a French chemist, about a century ago. In these the substance whose affinities are to be expressed is placed at the head of a column, and is separated from the rest by a horizontal line; beneath this line are arranged the bodies with which it is capable of uniting in the order of their respective forces of affinity; the substance which it attracts most strongly being placed nearest to it, and that for which it has the least affinity at the bottom of the column; thus, in the case of sulphuric acid, the affinities are exhibited in the following order:—

SULPHURIC ACID.

Baryta,
Strontia,
Potash,
Soda,
Lime,
Magnesia.

It would appear from this table, that baryta separates sulphuric acid from combination with all the substances placed below it, and that magnesia is separated from sulphuric acid by all that are above it. There are, however, many circumstances which interfere with the accuracy of tables thus constructed, and diminish their utility, since affinity is not an absolute force, but subject to anomalies and to modifications from various disturbing causes.

In the above, and many similar tables, the affinity of an acid for different bases is expressed; but on other occasions, the affinity of the same bases for different acids is required. In this case the alkali, earth, or metallic oxide, is placed at the head of the column, and the various acids are arranged according to their affinity for it.

There is yet another mode in which elective affinity is exerted. Certain compounds can scarcely be obtained at all, or with great difficulty, either by single affinity or single elective affinity, but are readily obtained by what is termed *double elective affinity*. There is a well-known mineral body called sulphate of strontia, which consists of sulphuric acid and the earthy base (or strictly speaking, metallic oxide) strontia, and they are combined by single affinity. Now potash has great affinity for the sulphuric acid of the sulphate of strontia; but if we mix them, no decomposition takes place, the potash being incapable, by single elective affinity, of detaching the sulphuric acid from the strontia. Again, carbonic acid and strontia have great affinity for each other, but if carbonic acid gas be passed through water in which powdered sulphate of strontia is diffused, it does not by single elective affinity separate the strontia from the sulphuric acid.

That decomposition, however, which single elective affinity cannot in this case perform, may be effected by double elective affinity, producing *double decomposition*. If, instead of acting upon the sulphate of

strontia with the carbonic acid and potash separately, we combine them and boil the powdered sulphate of strontia in a solution of the carbonate of potash thus formed, double elective affinity ensues, and two new compounds are formed—namely, sulphate of potash, which remains in solution, and carbonate of strontia, which, being insoluble in water, is precipitated in the state of a white powder. The double elective affinity which produces double decomposition will be illustrated by the annexed diagram.

Double elective affinity and decomposition are extensively employed in chemical operations; the preparation of various acids, such as the nitric and hydrochloric, and of a great number of saline compounds, depends upon the application of these modifications of chemical affinity. We shall now illustrate a position already stated, viz., that chemical affinity is not to be considered as an invariable power, but subject to causes which prevent, increase, or reverse its action; and it is on this account that tables of affinity express merely the order of decomposition, and not that of attraction under every circumstance. The causes now alluded to may be comprehended under *form* and *proportion*, and the modifying effects of cohesion, heat, electricity, and light.

With respect to *form*, it may be observed, that the solid state is unfavourable to the exertion of chemical affinity; and it was once supposed that two solid bodies could not act chemically upon each other. That this is not the case may be proved by adding lime to chloride of ammonium, for by their mutual action ammoniacal gas is plentifully evolved. Division is, however, in all cases favourable to chemical affinity: thus a mass of marble dissolves slowly in hydrochloric acid, but when reduced to powder the action is extremely rapid. The same effect is seen in the case of carbon in the three states of coke, charcoal, and tinder. Coke, the hardest and most compact of the three, can be ignited, that is, made to combine with atmospheric oxygen, only with difficulty, the lighter and more porous charcoal is much more easily ignited, whilst tinder readily takes fire from the smallest spark.

Minute division, then, so as to reduce the cohesion of a body, is in some cases necessary to the exertion of chemical affinity, and in all cases it increases the rapidity of its action.

Fluidity is always favourable to chemical action, and in most cases it is requisite that one body, at least, should be in that form.

Thus the tartaric acid and carbonate of soda contained in common effervescing powder do not act upon each other so long as the mixture remains in the solid state, but when the powder is thrown into water it dissolves, the affinity of tartaric acid for soda comes into play, and the carbonic acid is expelled.

The nascent state of bodies is one which is extremely favourable to the action of chemical affinity. Chlorine has affinity for silver, and the compound which they form, called chloride of silver, is white and insoluble in water; hydrogen has great affinity for chlorine, and they combine to form hydrochloric acid. If, however, hydrogen gas be passed into water holding chloride of silver in suspension, no change occurs, for the hydrogen has not, under these circumstances, the power of separating the chlorine from the silver.

If the hydrogen be evolved in the vessel which contains the suspended chloride of silver, it has then an opportunity of coming into contact with it in its *nascent state*, that is at the moment of its separation from combination, and before it has assumed the state of gas. Under these circumstances the hydrogen separates the chlorine from the silver, hydrochloric acid is formed, and metallic silver separated. The gases which constitute ammonia, namely, hydrogen and nitrogen, do not unite unless one of them, at least, is in the nascent state: thus if iron filings moistened with water are exposed to nitrogen gas confined over mercury, ammonia is produced, for the water is decomposed by the iron, its nascent hydrogen unites with the nitrogen to form ammonia, and its oxygen with the iron to form the oxide of that metal.

The nature of the compounds, arising from the chemical affinity and action of their elements, is greatly influenced by the *proportion* of the substances employed to produce them. When equal weights of sulphuric acid and alcohol are subjected to distillation, the product is sulphuric ether; double the quantity of acid, and oil of wine is obtained; use ten parts of acid to one of alcohol, and olefiant gas is formed by their mutual action. Again: if a mixture of two parts of nitre and one part of sulphuric acid be distilled, there are produced

nitric acid and sulphate of potash; but if a part of the sulphate of potash be dissolved in the nitric acid, nitrate of potash will be again formed, accompanied with bisulphate of potash.

There are several other cases which prove that the proportions of the substances which act chemically upon each other, greatly influence the nature and proportions of the new compounds formed: thus, when 100 parts of sulphate of baryta are boiled in a solution of 59 parts of carbonate of potash, 23 of the sulphate are decomposed and converted into 19.3 of carbonate. When also 85 parts of carbonate of baryta are boiled in a solution of 74 of sulphate of potash, decomposition also takes place, and there are formed 67 of sulphate of baryta, and 40 of carbonate of potash. In these experiments, then, it appears that decomposition cannot in either case be entirely effected, while the new compounds formed remain in mixture with the portions of the original salts which remain undecomposed. In other words, there takes place a partition of bases between the acids whose action is opposed to each other.

Cohesion, as the agent tending to produce the solid form of matter, exercises, as might be expected, a powerful controlling influence upon chemical affinity. It has been already stated, that solids act upon each other chemically with great difficulty, hence cohesion by retaining bodies in the solid form often presents a formidable barrier to their chemical union. Thus pieces of ice and quick-lime may be placed in contact without exhibiting any tendency to combine, although a violent action immediately ensues when an elevation of temperature causes the liquefaction of the ice. The most important and interesting effects of cohesion upon chemical affinity are, however, observed when the former force comes into play between substances in solution: thus, when nitrate of baryta is mixed with sulphate of potash, mutual decomposition of the two salts is effected, chiefly by the agency of cohesion, which solidifies and withdraws from solution a compound of the sulphuric acid, of the sulphate of potash, with the baryta of the nitrate of baryta. This controlling effect of cohesion is one of the most fertile sources of chemical change.

Heat, according to its degree and under various circumstances, produces very different effects on chemical affinity, and causes, increases, reverses, or prevents its action. If we mix oxygen and hydrogen gases, they will remain in a state of mixture for an indefinite period without combining; but if flame be applied to them they combine with explosion, and water is formed. When mercury is moderately heated in atmospheric air it is converted into peroxide, by combining with the oxygen of the air: heat the compound thus formed more strongly than was required for its production, and the affinity is destroyed; oxygen gas is given out, and the mercury returns to its metallic state. Mix solutions of chloride of calcium and carbonate of ammonia; double decomposition ensues; carbonate of lime and chloride of ammonium result. Evaporate the mixture to dryness, and heat the residue; the order of affinities is reversed, and chloride of calcium and carbonate of ammonia are reproduced: in this case, heat reverses the order of affinities. There is one instance, however, in which heat produces effects that are quite anomalous and irreducible to any idea of their dependence upon degree of temperature; it is this:—when the vapour of boiling water is passed over ignited iron, the water is decomposed; hydrogen, one of its elements, is evolved in the state of gas; and oxygen, the other, combines with the iron and converts it into oxide. Now if we ignite this oxide of iron and pass hydrogen gas over it, the oxide is decomposed, its oxygen combines with the hydrogen, and water is re-formed. No satisfactory explanation of these opposing results has hitherto been offered. These facts afford an illustration of the disturbing causes which very much limit the usefulness of tables of affinity. According to the first experiment, oxygen and iron combine in preference to oxygen and hydrogen, whereas it appears from the second that the affinity of oxygen for hydrogen exceeds that for iron. But it is evident that these statements are irreconcilable with each other; and as the temperature is in both cases the same, no variation of it can account for the incompatible results of the experiments.

Electricity possesses remarkable power over chemical affinity: if the electric spark be passed through a mixture of oxygen and hydrogen gases, it causes them to combine, and water is formed by their union. It is probable that this and some similar effects are produced by the heat which accompanies the electrical spark.

The action of electricity is much more remarkable in causing decomposition than combination, and especially that form of it which is termed voltaic electricity, or galvanism. The first substance decomposed by it was water. When two platinum wires are connected with the poles of a voltaic trough, and their unconnected ends are immersed in water, hydrogen gas is evolved at the negative, and oxygen gas at the positive wire. Many other compound bodies have been similarly decomposed; their elements separate at the opposite poles, and the same body always appears at the same pole: thus, in all decompositions, oxygen, chlorine, and the acids go over to the positive surface, while hydrogen, the metals, and the alkalies are found at the negative surface.

In common electrical attraction, the bodies attract each other in consequence of their opposite electrical states; and in the same manner, in the electro-chemical theory proposed by Sir H. Davy, it is supposed that acids and other substances which are attracted in

electrical decompositions to the positive pole, are negatively electrical at the moment of their separation from combination; and on the contrary, the alkalies, which are found at the negative extremity, are positively electrical.

It has, however, by no means been proved that chemical affinity is identical with electrical attraction; and we must yet consider the former as a peculiar species of attraction, subject indeed to the control of electrical agency, which is capable, not merely of decomposing compounds, but of suspending chemical action and reversing the order of affinities.

If sulphate of soda be dissolved in a blue vegetable infusion and subjected to voltaic electricity in a glass tube, it is soon found that the fluid at the positive pole becomes red, indicating the presence of an acid, while at the negative it is green, showing the action of an alkali. In this case the sulphate of soda is not only decomposed, but its constituents, while under electrical influence, appear to be incapable of recombining; for, by reversing the position of the tube, or the places of the wires, the fluid which was red will become green, and the green red; thus proving that, while under electrical influence, chemical affinity is suspended, for the acid and the alkali must have passed through the same solution without combining.

That affinity may be controlled by altering the electrical state of a body, is also proved by Sir H. Davy's very curious experiments on copper-sheathing, which, though they failed from unforeseen causes, are worthy of his genius. It appeared to Sir H. Davy that the copper was oxidised by the atmospheric air in the sea-water, and that then it combined with hydrochloric acid derived from chloride of magnesium, and formed with it subchloride of copper, and hence ensued the destruction of the metal. Now, as metals combine with acids only when oxidised, it occurred to Sir H. Davy, that if he could render the copper negative, which is the electrical state of the oxygen, they would not combine. This he effected by bringing the copper into contact with zinc or iron; these being rendered positive, the copper became negative, scarcely combined at all with oxygen, and was so little acted upon by the chloride of magnesium in sea-water, that when protected by only 1-1000th part of iron, oxidisement and conversion into subchloride were, to a certain extent, prevented.

The following will also serve as an example of the reversal of chemical affinity by electricity: Immerse a piece of copper in a solution of nitrate of silver; the copper is dissolved, and the silver precipitated; if we reverse the experiment, and put a piece of silver into a solution of nitrate of copper, no change is effected; if, however, the silver while immersed be touched by a piece of platinum, a voltaic circuit is formed, the order of affinity is reversed, the copper is precipitated, and the silver is dissolved.

Light is capable of controlling chemical affinity, both with respect to decomposition and combination. If a mixture of hydrogen and chlorine gases be exposed to the sun's rays, they combine with explosion, and form hydrochloric acid; this effect does not appear to be produced by the heat which accompanies the light, for a considerably higher temperature is not capable of producing the combination. With respect to the decomposing agency of light, it is well known that if pale nitric acid be subjected to it, it suffers decomposition to a certain extent, oxygen gas being evolved; it is also found that some metallic oxides which retain the oxygen with but slight force of affinity, evolve it and are reduced to the metallic state by the agency of light. Several of the beautiful processes of photography depend upon this effect of light in modifying chemical affinity.

In concluding the subject of chemical affinity, it is to be observed, that substances often combine in more than one proportion of each, and the quantities are governed by certain laws which have been considered under ATOMIC THEORY.

CHEMICAL ANALYSIS. Those chemical operations which have for their object the discovery or determination of the different kinds of matter of which any compound substance consists, are termed *analytical* operations, and this department of chemical science is called chemical analysis.

Substances are subjected to chemical analysis for the purpose of determining (1) what constituents they contain, and (2) the amount of such constituents. The processes adopted for the first of these objects constitute *qualitative*—those for the second, *quantitative analysis*. Both qualitative and quantitative analysis may be only partial; that is, in qualitative analysis it may only be required to detect one or more constituents in a compound substance, or, in quantitative analysis, the estimation of the amount of one or more constituents may be desired. An example of the first is the detection of poisons in animal substances; of the second, the determination of the commercial value of a manure. It follows that very different methods may have to be employed in the partial examination of a substance either qualitatively or quantitatively, according to the particular constituents which have to be sought for or estimated. The examination of a substance, on the other hand, may be total, either in respect to the nature or amount of the constituents it contains; that is, we may have to determine either qualitatively or quantitatively, the whole of the substances present.

Further, in both divisions of analysis, different methods have to be employed, according as it is required to detect or estimate the proximate, or ultimate (elementary) constituents. For instance, in the

examination of a mineral, we may be satisfied with the detection of iron, or with the estimation of its amount; or, on the contrary, it may be required to be known in what stage or stages of oxidation the iron exists, or how much of the different oxides are contained in the mineral.

It is, however, clear that, whatever be the kind of information sought regarding the nature of a substance, the processes to be adopted will have greater or less similarity according as the substances examined are more or less alike; and it follows hence that as substances may be grouped together in classes, whose members resemble one another chemically; so the processes of analysis applied to the members of the same class bear also a likeness to one another.

Thus those substances which were (historically) first derived from the animal and vegetable kingdoms, and the artificially prepared bodies resembling them in composition—the so-called organic bodies—contain invariably carbon, generally hydrogen, frequently oxygen and metals, sometimes nitrogen, and occasionally sulphur, chlorine, phosphorus, &c. In many instances, such bodies may have to be divided into their proximate constituents: in such cases special knowledge must be had of the nature and behaviour of these constituents. But a question more frequently to be solved with regard to organic bodies, is the determination, qualitatively or quantitatively, of their ultimate constituents or elements. The importance of this species of analysis, and the similarity of the methods employed upon the different organic substances, renders a special article necessary for their consideration. [ORGANIC ANALYSIS.]

Again, the physical state in which a body is presented for analysis—whether as a solid, a liquid, or a gas, renders corresponding variations of method and apparatus necessary. This is especially the case with gases and vapours, and hence a separate article will be devoted to this branch of analysis. [GASOMETRIC ANALYSIS.]

Inasmuch as most inorganic chemical compounds consist of one or more bases, acids or salts [ACID; BASE; SALT], qualitative and quantitative inorganic analysis consists mainly of the detection, separation, and estimation, of the various bases and acids (for the detection and separation of these of course includes those of the salts resulting from their union). Again, as most bases are metal, or contain a metal, the detection, separation, and estimation of the metals is of the first importance in qualitative and quantitative analysis.

It is proposed, in the limits of the present article, to give a general outline of the chemical analysis of inorganic liquids and solids. To do this it will be necessary to describe, in qualitative analysis—1st, how the bases are separated into groups; 2nd, how the members of the groups are separated from one another; 3rd, the detection of the most important acids. A general sketch will then be given of the principles and practice of quantitative analysis.

Qualitative analysis. The chief means used in separating the metallic bases from one another is founded upon the difference of solubility of their analogous compounds in the same medium.

Thus if the metals be made to combine with oxygen, the so-formed oxides are found to be soluble in water in the following different degrees:—

	Very Soluble.	Less Soluble.	Difficultly Soluble.	Insoluble.
Oxides of	K, Na, NH ₄ *	Ba, Sr, Ca	Mg	Al, Cr, Fe, Mn, Zn, Ni, Co, Sn, Pt, Au, Hg, Pb, Ag, Bi, Cd, Cu.

Again, on examining the chlorides of the metals, we find that—

	Very Soluble.	Difficultly Soluble.	Insoluble.
Chlorides of	K, Na, NH ₄ , Ba, Sr, Ca, Mg, Al, Cr, Fe, Mn, Zn, Ni, Co, Pt, Au, Hg, (HgCl), Cd, Cu	Pb	Hg, (Hg ₂ Cl), Ag.

The compounds formed by the union of other elements, or groups of elements (acids), with the metals, show again a different order of solubility; and it is by this difference in solubility in different media, of the analogous compounds of the metals, that their separation from each other is chiefly effected.

Thus, if a solution contains silver and copper, and by any means both the metals are converted into chlorides, it is clear that, the chloride of silver being an insoluble substance in water, may be separated from the soluble chloride of copper; that is, the silver may be separated from the copper. When one metal has been thus converted into an insoluble compound in a solution, it is said to be precipitated or thrown out of solution in a solid form; and it may generally be separated from the soluble compounds of other metals present by filtration through unsized paper.

Very frequently analogous compounds of different metals, which are equally soluble or insoluble in water, show different degrees of solubility in other media. Often an acid or alkaline medium affects differently in this respect analogous compounds of bodies which are equally soluble or insoluble in water: and this is in most cases due to the difference which such compounds possess in their liability to be

decomposed by such media: sometimes, however, to a true difference in the solvent power of the medium. An example of the difference of solubility in another medium of analogous compounds (which are equally insoluble in water), is furnished by the sulphides of zinc and of cadmium. The former is dissolved in (and decomposed by) hydrochloric acid, the latter is unchanged. Again, the sulphides of tin and copper are insoluble both in water and hydrochloric acid. But the former is soluble in caustic potash (and combines with it); the latter is insoluble. Further, the chlorides of barium and of strontium are both soluble in water; but the latter alone is dissolved by alcohol.

The difference of solubility of the analogous compounds of the different metals in water, acids, and alkalis is most marked in the case of the sulphides. On this account, and because a metal is often characterised by the colour of its sulphide, one of the earliest processes in the detection and separation of the metals is their conversion into sulphides.

If we look at the following series of facts, we at once see the possibility of separating the metals into families or groups:—

I. Of all the metals, the following chlorides alone are insoluble, or nearly so, in cold water, and in dilute hydrochloric and other acids, AgCl, PbCl, Hg₂Cl. A.

II. Of all the metals not in A, the following sulphides alone are insoluble in hydrochloric acid, HgS, BiS, CdS, CuS, AsS₃(S₅), SbS₃(S₅), SnS(S₂)PtS₂AuS₃. B.

III. Of all the sulphides in B, the following alone are soluble in alkalis and alkaline sulphides, AsS₃(S₅), SbS₃(S₅), SnS(S₂), PtS₂, AuS₃. C.

IV. Of all the metals not in A and B, the following alone are precipitated by excess of ammonia (as oxides), even when soluble salts of ammonia are present, Fe₂O₃, Cr₂O₃, Al₂O₃. D.

V. Of all the metals not in A, B, and D, the following alone form sulphides which are insoluble in water, MnS, ZnS, NiS, CoS. E.

VI. Of all the metals not in A, B, D, and E, the following alone form carbonates which are insoluble in water, even in the presence of soluble salts of ammonia, BaO CO₂, SrO CO₂, CaO CO₂. F.

VII. Of all the metals not in A, B, D, E, F, the following alone forms an insoluble arseniate and phosphate, Mg. G.

VIII. The remaining metals, whose chlorides, sulphides, oxides, carbonates, phosphates, and arseniates are soluble, are the alkaline metals, K, Na, NH₄. H.

According to a part of Berthollet's doctrine of the conditioning of chemical change, the entire union of one of two bodies in a solution with another is dependent upon the insolubility of the resulting compound. So that by bringing two compounds together which by reciprocal interchange of their constituents may give rise to an insoluble new body, that body will be formed.

A. If, therefore, we have a solution containing all the metals, and add to it an excess of hydrochloric acid, those metals whose chlorides are insoluble in water and hydrochloric and other acids, will be precipitated as chlorides, and, as such, may be separated by filtration from all the other metals.

B. and C. On passing sulphydric acid through the acid, filtrate from the precipitated chlorides A, until it is perfectly saturated with the gas; all the metals of the group B, and none others, will be precipitated as insoluble sulphides, and may be separated from all the remaining non-precipitated metals by filtration.

D. The filtrate from B and C contains all the remaining metals, and is saturated with sulphydric acid, which, though it has not precipitated the iron, has reduced it to the state of protoxide. On boiling this filtrate to expel the sulphydric acid, then boiling with nitric acid to peroxidise the iron, and adding chloride of ammonium and ammonia in excess, the metals D are precipitated as oxides, and may be separated from the remaining metals by filtration. If the hydrosulphuric acid be not expelled, an alkaline sulphide (sulphide of ammonium), would be formed on the addition of ammonia, which would precipitate the metals E. If the iron be not peroxidised, a portion of the protoxide would be dissolved by the ammoniacal salts formed on the addition of ammonia, and would appear in the filtrate. If a large quantity of chloride of ammonium be not added, in addition to the salts of ammonia formed, the manganese will not remain entirely non-precipitated.

E. The oxides D having been separated by filtration, sulphide of ammonium added to the filtrate from D precipitates the metals E as sulphides.

F. On boiling the filtrate from E with an excess of carbonate of ammonia, the metals F are precipitated as carbonates. Magnesia is not precipitated on account of the soluble ammoniacal salts present.

G. The filtrate from the alkaline carbonates F, on being treated with arseniate of ammonia, forms a precipitate of arseniate of magnesia and ammonia. G.

H. The filtrate from G on evaporation to dryness and ignition until all the arsenical and ammoniacal salts introduced are volatilised or decomposed, contains the alkalis H.

Since ammonia and its salts have been employed in the separation of the groups, ammonia itself must be tested for in the original solution, or in the filtrate from A.

It is self-evident that in every case where a reagent is used to separate a group, that reagent must be used in excess, that is, in more than sufficient quantity to effect the separation (precipitation or solution),

* The salts of the quasi-metal ammonium (NH₄) are so analogous to those of the metals proper, and ammonium is of so frequent occurrence in nature, that it is included among the metals.

in order to ensure its completeness. Hence, as a general rule, when, for instance, a precipitation has been effected and the insoluble compound separated by filtration, the filtrate should be treated with some more of the same reagent which has been employed in the precipitation, and if the latter has been perfect, no further precipitation will be thereby produced.

It is also clear that when a precipitate has been formed in a solution and separated from the non-precipitated constituents by filtration, the precipitate is still moistened with the solution of the non-precipitated portions, and must be therefore cleansed from them by washing with water before further examination.

Figs. 1, 2, 3, show the successive foldings by which a filter is formed

from a round piece of unsized paper; 4 shows how the folds are opened so as to form a conical sack, having three folds of paper on one side and one on the other, and how it is placed in a glass funnel. Fig. 5, the washing bottle, is a narrow-necked glass flask, through

whose air-tight cork two tubes, open at both ends, pass; the one, A C, having its internal end beneath the water, the other, B, just passing through the cork. Air forced into B from the mouth presses the water into C, and projects it from A, where the tube is narrowed to a fine orifice.

The various substances added in order to separate the above groups of metals from one another, and each of which consequently behaves in the same manner to the members of the group which it separates, are called the *general reagents* of those groups. Thus carbonate of ammonia is the general reagent for the alkaline earths, barium, strontium, and calcium.

Space will not admit of a more detailed description of the separation of the various groups from one another, but from the following summary an idea may be formed of the process in each group.

A. Of the chlorides—chloride of lead (PbCl), chloride of silver (AgCl), and subchloride of mercury (Hg_2Cl), the chloride of lead alone is soluble in boiling water: of the two—chloride of silver and subchloride of mercury, chloride of silver alone is soluble in ammonia, subchloride of mercury being blackened but not dissolved by it.

B. Of the sulphide of mercury (HgS), bismuth (BiS), cadmium (CdS), and copper (CuS), the sulphide of mercury alone is insoluble in strong nitric acid. From the nitrates of bismuth, cadmium, and copper, the bismuth alone remains permanently precipitated (as an oxide) on the addition of an excess of ammonia. From the ammoniacal solutions of cadmium and copper, the cadmium alone is precipitated (as a carbonate) by carbonate of ammonia.

C. The sulphides of arsenic, antimony, tin, gold, and platinum, dissolved in sulphide of ammonium are all precipitated as insoluble sulphides on the addition of hydrochloric acid; of these sulphides that of arsenic alone is soluble in carbonate of ammonia. Of the remaining sulphides, those of antimony and tin are converted into oxides (SbO_3 , SnO_2) on ignition with nitrate of ammonia, while the sulphides of gold and platinum are reduced to the metallic state. Oxide of antimony is soluble in tartaric acid, while neither binoxide of tin nor metallic gold or platinum are dissolved by it. But gold and platinum are both dissolved by nitro-hydrochloric acid, in which binoxide of tin is insoluble.

D. The sesquioxides of iron, chromium, and aluminium, are soluble in hydrochloric acid. All these three metals are precipitated by cold

caustic potash (as oxides) from the so-formed chlorides, the oxide of iron alone is insoluble in excess. Boiling caustic potash precipitates the oxide of chromium, but not the alumina.

E. The sulphides of zinc, nickel, cobalt, and manganese, are dissolved as chlorides by nitro-hydrochloric acid. From this solution carbonate of ammonia precipitates them all; but when added in excess, dissolves them all excepting manganese. Caustic potash precipitates oxides of nickel, cobalt, and zinc, and in excess only dissolves the oxide of zinc. Hydrochloric acid dissolves the oxides of nickel and cobalt; cyanide of potassium precipitates and dissolves in excess both nickel and cobalt from the acid solution of their chlorides. An acid added in excess to the cyanide of potassium solution, only precipitates the nickel as cyanide.

F. The carbonates of barium, strontium, and calcium are soluble in hydrochloric acid, the corresponding chlorides being formed. In a neutral or ammoniacal solution of these chlorides, chromate of potash precipitates the barium alone. Of the strontium and calcium, sulphate of potash precipitates the strontium alone, from dilute solutions.

G. Requires no separation.

H. It will be well to describe more fully, by way of example, the separation of the members of one group. For this purpose we will take that of the alkaline metals, potassium, sodium, and ammonium.

Ammonium is first tested for; this is done by adding caustic potash, soda, or lime to a portion of the solution, and heating. With whatever acid the ammonium is combined, the latter is liberated by the free base added, and is detected in the form of ammoniacal gas by its peculiar smell, by its alkaline reaction in turning reddened litmus blue, and by its fuming when a rod moistened with hydrochloric acid, of sufficient strength to diffuse sensibly in the air, is held in its presence. If no ammonia is found in this manner, the original solution is tested for potash. To a portion of it tartaric acid is added, and the sides of the vessel vigorously rubbed with a glass rod. A white crystalline precipitate of the tartrate of potash, whose formation is much accelerated by the agitation, shows the presence of potash. To a fresh portion bichloride of platinum (PtCl_2) is added, the solution is gently evaporated to dryness, and a mixture of equal parts of alcohol and ether is added; a heavy yellow crystalline insoluble residue shows the presence of potash. A perfectly clean platinum wire is dipped in a portion of the original solution (previously concentrated by evaporation), and held in the outer flame of the blowpipe. If on looking at it with the naked eye the flame appears yellow, this shows the presence of soda; if purple, it is evidence of potash. If the flame be yellow, potash may be present, because the yellow colouring power of the soda is much greater than the purple colouring power of the potash. If both are present, the purple colour due to the potash may be seen by viewing the flame through a piece of blue glass (cobalt glass), which intercepts the yellow light produced by the soda, and allows the purple of the potash to be recognised.

If ammonia was found in the first instance, it must be got rid of before testing for potash; because, like potash, it forms insoluble compounds with tartaric acid and with bichloride of platinum. This is done by evaporating the original solution to dryness and igniting it. The non-volatile residue is then dissolved in water, and examined as above for potash and soda.

After the metals have been separated into groups by the general reagents, and the members of each group separated from one another according to the preceding outline, the presence of the different metals found should be confirmed by the application of as many characteristic reactions as possible, that is, by applying special reagents to the solution which has been submitted to analysis; for when a substance shows a characteristic behaviour towards any reagent, the like of which is not shared by any other substance, the reagent is called special with regard to the substance. It follows that when only one or few substances are present or have to be tested for, the application of certain appropriate special reagents is often sufficient to indicate their presence or absence, and saves the time and trouble of the systematic separation above sketched, in which the whole of the metallic bases are supposed to be present.

The following are some characteristic reactions of the metallic bases, which reactions are not included in the above scheme:—

Copper is precipitated from an acid solution in the metallic state upon metallic iron. It is precipitated as a green carbonate by the carbonate of a fixed alkali; as a greenish blue hydrated oxide by a caustic fixed alkali in the cold; as a black oxide when heat is employed. It forms a mahogany-coloured precipitate with ferrocyanide of potassium.

Cadmium is a volatile easily oxidisable metal, whose sulphide is yellow.

Bismuth is precipitated from its acid solutions by water, basic insoluble salts being formed.

Mercury is a volatile metal; all its compounds are reduced to the metallic state either by heat alone, or in the presence of alkalis or alkaline carbonates. The salts of its peroxide form a red chromate, a red iodide, and a yellow oxide. It is precipitated in the metallic state by metallic copper.

Lead is precipitated as a white hydrated oxide by a fixed alkali. It forms white insoluble carbonates and sulphates. Its chromate and iodide are yellow and insoluble; most of its compounds are reduced to

the metallic state by heat in the presence of carbon, or from solutions by metallic zinc.

Silver is reduced from all its compounds at a red heat by alkaline carbonates.

Gold forms a purple precipitate with stanni-stannous chloride.

Platinum in acid solutions forms a yellow precipitate with soluble salts of ammonia and potash.

Tin, see *Gold*. Tin is reduced from most of its compounds by red-hot charcoal.

Antimony } The soluble compounds are decomposed by nascent
Arsenic } hydrogen, and the reduced metal forms with it antimonuretted and arsenuretted hydrogen, which are inflammable gases. Arsenuretted hydrogen reduces salts of silver. Metallic arsenic in a fine state of division is soluble in chloride of lime. Arsenious acid forms a yellow precipitate in ammonio-nitrate of silver, and a green one in ammonio-sulphate of copper. It is precipitated as a metal by metallic copper. The sulphide of antimony is converted into a volatile chloride by dry hydrochloric acid.

Aluminium. The oxide of aluminium, when heated with a salt of cobalt, becomes of a bright blue colour.

Chromium. The tetroxide of chromium, or chromic acid, forms characteristically coloured salts (chromates), with various metallic bases. The sesquioxide and its salts are converted into chromate of potash by fusion with nitrate of potash.

Iron. The sesqui-salts of iron give a blood red colour with sulphocyanide of potassium, and a blue precipitate with ferrocyanide of potassium. The proto-salts are turned brown with nitric acid, and give a blue precipitate with ferricyanide of potassium.

Manganese. The sulphide of manganese is flesh-coloured. All compounds of manganese are converted into the bluish-green manganate of soda, on fusion with a mixture of carbonate of soda and nitrate of potash.

Cobalt imparts an intense blue colour to a bead of borax in the blowpipe flame.

Nickel. The oxide of this metal dissolves in ammonia with a blue colour.

Zinc is reduced to the metallic state by red-hot charcoal. The metal is volatile and easily oxidisable; its sulphide is white. Its oxide is yellow whilst hot, but white when cold.

Magnesia, when heated with nitrate of cobalt in the blowpipe flame, becomes flesh-coloured.

Lime forms an oxalate, insoluble in alkaline solutions and in acetic acid. It gives a red colour to the blowpipe flame.

Strontia. Its chloride imparts a crimson colour to the flame of alcohol.

Baryta forms a sulphate insoluble in water, alkalies, and acids.

For the special blowpipe reactions of the metallic bases, see BLOWPIPE.

The method of qualitative analysis thus briefly sketched, will be better understood by supposing we have to examine a solution containing a member of each group, under the supposition that we are, at the commencement, ignorant as to what it contains.

Let the solution contain,—

K, Sr, Mg, Al, Mn, Sn, Ag, HgO, Bi.

A portion of the solution is heated with caustic potash, no ammonia is evolved, therefore ammonia is absent.

To the remainder an excess of hydrochloric acid is added, a white precipitate (A) is formed.

The filtrate from A is saturated with hydrosulphuric acid, a brown-black precipitate (B) is formed.

The filtrate from B is boiled alone, and then with nitric acid, chloride of ammonium is added, and then ammonia. A white precipitate (C) is formed.

To the filtrate from C, sulphide of ammonium is added, a flesh-coloured precipitate (D) is formed.

The filtrate from D is boiled with carbonate of ammonia, a white precipitate (E) is formed.

To a portion of the filtrate from E phosphate of soda is added, a white precipitate is formed. To the remainder arseniate of ammonia is added, a white precipitate (F) is formed.

The filtrate from F is evaporated to dryness, ignited and dissolved in water, giving solution G.

The separation of the metals into the groups has, therefore, been effected; the separation of the different members of the groups now follows.

The precipitate A is washed with boiling water on the filter. Sulphuric acid gives no precipitate in the filtrate, therefore *lead* is absent. Ammonia added to A does not blacken it, therefore *suboxide of mercury* is absent, but dissolves it, therefore *silver* is present. (Confirmatory: hydrochloric added to the ammoniacal solution, reprecipitates the silver as chloride; this is reduced to the metallic state on charcoal; dissolved in nitric acid, neutralised with ammonia, and the characteristic chromate and iodide of silver found on the addition of soluble chromates and iodides.)

The precipitate B is digested with sulphide of ammonium, it is filtered and hydrochloric acid added to the filtrate throws down a

brown precipitate (G). The part of B insoluble in sulphide of ammonium is digested with nitric acid; a black residue remains, showing the presence of protoxide of *mercury*. (Confirmatory: the black insoluble mass is dried, mixed with carbonate of soda, and heated in a dry tube; metallic mercury volatilises and condenses on the cold part of the tube.) The filtrate from the sulphide of mercury is treated with an excess of ammonia, a white precipitate is formed, showing the presence of *bismuth*. (Confirmatory: the precipitate is separated by filtration, dissolved in nitric acid, and dropped into water, a white precipitate is formed. On adding carbonate of ammonia to the filtrate from the bismuth, no precipitate is formed, therefore *cadmium* is absent, on boiling the same solution with caustic potash no precipitate is formed, therefore *copper* is absent.)

The precipitate got by adding hydrochloric acid to the portion of B dissolved in sulphide of ammonium is digested with carbonate of ammonia and filtered, hydrochloric acid produces no precipitate in the filtrate, therefore *arsenic* is absent. That which has not been dissolved in carbonate of ammonia, is heated to redness with nitrate of ammonia, then digested with tartaric acid and filtered: hydrosulphuric acid throws down no sulphide from the filtrate, therefore *antimony* is absent. That which has not been dissolved in tartaric acid, is boiled in nitro-hydrochloric acid and filtered. Neither chloride of ammonium, nor protochloride of tin affect the filtrate, therefore *platinum* and *gold* are absent. That which has not been dissolved in nitro-hydrochloric acid is fused on charcoal with carbonate of soda: on scraping the fused mass into a mortar and washing with water, a malleable metallic globule is found, which shows the presence of *tin*. (Confirmatory: the globule is boiled with hydrochloric acid; on adding chloride of gold a purple colour is formed.)

The precipitate C is dissolved in hydrochloric acid; cold caustic potash produces a precipitate which dissolves in excess, therefore *iron* is absent: on boiling the caustic potash solution, no precipitate is formed, therefore *chromium* is absent; on adding an excess of hydrochloric acid and then an excess of ammonia, a white precipitate is formed, therefore *aluminium* is present. (Confirmatory: the precipitate is collected on a filter, dried and heated before the blowpipe with a solution of cobalt; a blue colour is produced.)

The precipitate D is dissolved in nitro-hydrochloric acid, and then boiled with an excess of carbonate of ammonia, a white precipitate is formed, therefore *manganese* is present. (Confirmatory: a part of the so-formed carbonate of manganese is fused with nitrate of potash and carbonate of soda, a bluish-green mass is obtained of manganate of soda; another portion of the manganese precipitate is fused in the outer blowpipe flame with borax, an amethyst bead is formed.) The filtrate from the manganese is boiled with an excess of caustic potash, no precipitate is formed, therefore *nickel* and *cobalt* are absent: sulphide of ammonium added to the caustic potash solution gives no precipitate, therefore *zinc* is absent.

The precipitate E is dissolved in hydrochloric acid, made alkaline by ammonia, and treated with chromate of potash, no precipitate is formed, therefore *barium* is absent. Sulphate of potash is added, and the liquid allowed to stand for some hours; a precipitate is formed, showing the presence of *strontium*. The filtrate from the strontium precipitate is made alkaline with ammonia, and then treated with oxalate of ammonia: no precipitate is formed, therefore *lime* is absent.

The precipitate F requires no examination, its formation proves the presence of *magnesium*.

The filtrate from F is evaporated to dryness, and ignited to expel the ammoniacal and arsenical salts; when the residue is dissolved in a little water, it gives a precipitate with tartaric acid and also with bichloride of platinum, therefore *potassium* is present. (Confirmatory: a wire dipped into the solution and held in the flame turns it violet, which shows also the absence of sodium.)

When the constituents of a body are quite unknown, a preliminary examination of it in the dry way often saves time by giving some clue to the bodies which are present. Thus the easy fusibility of a substance when heated on charcoal, generally points to the presence of the fixed alkalies. If it be heated in a narrow tube closed at one end, with carbonate of soda, ammonia and mercury, if present, are volatilised. If cyanide of potassium is added arsenic is volatilised, and so on.

If the body to be analysed is in the solid form it is examined as follows: It is boiled with water; if it dissolves completely, the method given above is at once applied. If it is only partly soluble in water, the insoluble part is boiled with hydrochloric acid and filtered; if anything remains insoluble in hydrochloric acid, it is treated with nitric acid, and should this leave anything undissolved, the residue is boiled with nitro-hydrochloric acid. The four extracts so got from the same quantity of the substance by these reagents are then mixed, and if any precipitation ensues, it is examined for the metals in A. Any substance which resists the action of all these reagents when successively used, does so in consequence of its containing some acid or non-metallic element. The method of analysing such bodies is best considered after the description of the behaviour of the acids.

Detection of acids. Just as a large number of the bases are chiefly detected by the peculiarity of their behaviour towards certain acids or salts containing them, so acids are in general detected by the peculiarity of their behaviour towards certain bases or salts containing the latter. Hence it frequently happens that an acid and a base are

mutually special reagents. And just as most of the chemical characters of a base are exhibited in its soluble salts, so most of those of the acids appear in their soluble compounds (for the so-called free acids are hydrogen salts). But in regard to their physical properties, this is not the case; for many acids when in such combination with hydrogen alone, that is, as free acids, are very much more volatile than when in union with metallic bases.

It is almost self-evident that all those acids which in the free state (under the ordinary conditions of pressure and temperature) are gaseous, are also volatile. When such an acid is by any means expelled from combination (from its base) more or less of it will be volatilised according as the free acid is less or more soluble in the liquid in which it is liberated; and this solubility, as with other gases, depends upon the nature of the acid, upon the nature of the liquid in which it is freed (principally in regard to the amount of solid matter it holds in solution), and upon the temperature to which the freed acid is subjected (leaving out of account the pressure upon it). According to their solubility in most liquids, and therefore, *ceteris paribus*, their degree of volatility, volatile acids may be divided into five tolerably well defined groups.

I. Most volatile, and therefore most easily driven off from solution when in the free state: Carbonic acid (CO_2), hydrosulphuric acid (HS), sulphurous acid (SO_2).

II. More soluble, therefore less volatile; requiring a higher temperature, or more concentrated solution for expulsion: Hydrocyanic acid (HCy), hydriodic acid (HI), hydrobromic acid (HBr), hydrochloric acid (HCl), nitric acid (HONO_2), hydrofluoric acid (HF).

III. Much more difficultly volatile: Sulphuric acid (HOSO_3).

IV. Further, there are the non-volatile: Boracic acid (BoO_3), phosphoric acid (PO_5), silicic acid (SiO_3).

V. Those which are decomposed by heat, Chloric acid (ClO_3), Oxalic acid (HOC_2O_3).

As a general rule, the less soluble and more volatile an acid is, the more readily is it driven from its base by a more soluble or less volatile acid. Hence sulphides, sulphites, and carbonates, are generally decomposed, even at low temperatures, by almost any other acid such as one of the second group. These again are expelled from their salts by sulphuric acid, when in concentrated solution, or when heat is applied. The latter is expelled and volatilised at a strong heat, by one of the third group.

Hence the gases which are given off on adding hydrochloric acid to a dilute solution of a substance are to be examined for group I. Those which are expelled from a strong solution, or on heating (between 100° – 305° Fahr.) with sulphuric acid (for, as before stated, concentration has here the same effect as heat), are to be examined for II. For the less volatile III. the non-volatile IV. and the decomposed V. other methods are employed.

The detection of the individual acids is based upon their following characters:—

Free Carbonic acid precipitates lime from alkaline solutions, and dissolves it in excess; it is non-inflammable, and extinguishes flame.

Free hydrosulphuric acid gives the characteristically coloured sulphides with the metals (described under the bases); its smell is peculiar; it is inflammable, being converted, on combustion, into sulphurous acid and water.

The sulphurous acid is unflammable; of peculiar smell; forms an insoluble sulphite with lime; and decomposes hydrosulphuric acid, solid sulphur being liberated.

Free hydrofluoric acid has the power of attacking silicic acid and the silicates, forming gaseous fluosilicic acid. If therefore a piece of glass be partly coated with wax, and exposed to the gas given off when a substance is warmed with strong sulphuric acid, it will be etched in those parts which are unprotected, if the original substance contain a fluoride.

Nitric acid. As all nitrates are soluble, nitric acid cannot be precipitated by any base. Free nitric acid oxidises metallic copper, being itself deoxidised, and the formation of red fumes attend such deoxidation. Free nitric acid is also turned brown by the protosulphate of iron. On adding, therefore, strong sulphuric acid to a nitrate and heating with metallic copper, red fumes are given off. If a solution of protosulphate of iron be poured upon another cold portion to which sulphuric acid has been added, a brown ring is formed at the junction of the two liquids.

Hydrocyanic acid. When a cyanide is treated with strong sulphuric acid, hydrocyanic acid is given off. Free hydrocyanic acid combines with sulphide of ammonium, containing an excess of sulphur (over the monosulphide), and forms with it sulphocyanide of ammonium, a substance which, after the excess of sulphide of ammonium is expelled by heat, gives a blood-red colour with the persalts of iron. Hydrocyanic acid forms a white cyanide of silver, which is insoluble in water and acids, but soluble in ammonia. It is decomposed by heat alone.

Hydrochloric and hydrobromic acids both form salts with silver which are insoluble in water and acids, but soluble in ammonia. The bromide and chloride of silver are decomposed on being fused with carbonate of soda, the metal being reduced and the bromide and chloride of soda formed. Bromides and chlorides, when heated with

sulphuric acid and binoxide of manganese give off bromine and chlorine respectively.

Hydriodic acid. Iodide of silver is yellow, insoluble in acids, and very difficultly soluble in ammonia. Iodides are decomposed, giving off free iodine when heated with binoxide of manganese and strong sulphuric acid.

Sulphuric acid in solution precipitates baryta from solution as a sulphate, which is insoluble in hydrochloric acid. Sulphates are converted into sulphides by fusion with carbon.

The members of group IV. form baryta and lime, salts which are insoluble in water and ammonia, but soluble in free hydrochloric acid.

Silicic acid in the free state, after drying, is insoluble in water and acids, except hydrofluoric acid. It forms a transparent colourless bead when fused with carbonate of soda. Silicates which are not decomposed by acids give up their bases to carbonic acid when fused with an excess of carbonate of soda; the silicic acid itself combining with the soda to form a basic silicate of soda from which an acid separates the base, leaving the silicic acid, after drying, as an insoluble powder.

Phosphoric acid. Phosphoric acid forms a yellow phosphate of silver, which is soluble in nitric acid and in ammonia. The phosphates of the alkaline earths, and of iron, chromium, and alumina, are soluble in acids, but not in ammonia. Compare magnesia.

Boracic acid. The borates of the alkaline earths, and of iron, chromium, and alumina, are soluble in acids, but not in ammonia. If a borate be treated with strong sulphuric acid, the boracic acid is liberated. Free boracic acid has an alkaline reaction, and gives a characteristic green colour to the flame of alcohol. The borate of silver is soluble in nitric acid.

Chloric acid, like nitric acid, forms an insoluble salt; a chlorate on being ignited gives off its oxygen, and is converted into a chloride.

Oxalic acid forms with lime an oxalate which is insoluble in water, but soluble in acids (excepting acetic acid). Many oxalates on being heated give off carbonic oxide, and are converted into carbonates.

Space will not allow a detailed description of the separation of the acids; moreover they do not admit of a systematic separation, similar to that described with the bases. The following outline may serve to give some idea of the process employed. We will at first suppose that the alkaline earths, alumina, and the oxides of chromium and iron are absent.

I. The substance is treated with dilute hydrochloric acid; if a gas is evolved on warming, it is passed through lime water. A precipitate is formed, both with carbonic and sulphurous acids. The latter is detected by its bleaching power, its peculiar smell, and by its depositing sulphur when mixed with hydrosulphuric acid. A piece of paper moistened with a solution of acetate of lead is held in the evolved gas; if it is blackened, hydrosulphuric acid is present.

II. Another portion is evaporated to dryness with a fixed alkali, and treated with strong sulphuric acid; the gas, if any is evolved, is tested as before described for hydrocyanic and hydrofluoric acids.

III. Another portion is treated with strong sulphuric acid, and distilled (this is at first done with a small quantity, lest a chlorate be present, in which case the action is attended with explosion), water being placed in the receiver. A portion of the distillate is tested for nitric acid with sulphate of iron and metallic copper as already described. To another portion nitric acid and nitrate of silver are added. If any precipitate is formed, it is collected and treated with dilute ammonia. The insoluble portion is treated with strong sulphuric acid and binoxide of manganese. Iodine is evolved if hydriodic acid was present (iodine would also be evolved on distilling the substance with sulphuric acid). Nitric acid added to the ammoniacal filtrate precipitates the bromide and chloride of silver, in which the halogens are either at once detected in the same manner as was the iodine, or else after combining them with sodium by fusing the silver salts with carbonate of soda.

IV. To another portion, hydrochloric acid must be added (if a precipitate be formed it must be removed by filtration), and then solution of chloride of barium; if a precipitate is formed, sulphuric acid was present.

V. A portion from which the carbonic acid has been expelled is neutralised with ammonia, made acid with acetic acid, and treated with chloride of calcium. If a precipitate is formed, it is oxalate of lime. In this case it is collected, dried, and heated in a closed tube; carbonic oxide is thereby driven off, and may be inflamed; a white carbonate of lime remains, which gives off its carbonic acid when treated with hydrochloric acid. The filtrate from the oxalate of lime is evaporated to dryness, at 212° , with hydrochloric acid. If a residue remains which is insoluble in water, silicic acid is present; this gives a clear glass when fused with carbonate of soda. A portion of the dry residue is moistened with alcohol, treated with sulphuric acid, and inflamed; a green flame shows the presence of boracic acid. To another portion of the dry lime salt, chloride of iron is added, and then acetate of soda in excess. On boiling to expel the liberated acetic acid, phosphate of iron (and subacetate) is precipitated. This is filtered from the chloride of calcium formed, and after washing, decomposed by sulphide of ammonium. The iron remains insoluble as a sulphide; the phosphoric acid is in the filtrate as the phosphate of ammonia, from which a soluble salt of magnesia precipitates the phosphoric acid.

The acids formed by the union of metals with oxygen, such as chromic, manganic, arsenious, &c., are found when the examination for the bases is performed. Moreover, when certain acids are present along with certain bases, and the salts so formed are soluble in hydrochloric acid and other acids, but insoluble in ammonia, it is clear that in the examination for the bases, when ammonia is added to precipitate the oxides of chromium, aluminium, and iron, salts of such a nature will be precipitated along with, or in place of these three oxides. The salts having this property are formed by the union of any of the three acids,—

Phosphoric	} with any of the bases,	Baryta	Alumina
Boracic		Strontia	Oxide of chromium
Oxalic		Lime	Sesquioxide of iron,

as also phosphoric acid when in combination with magnesia.

Hence the precipitate obtained by ammonia must be examined for these acids and bases, as well as for the simple oxides of chromium, iron, and aluminium. For this purpose it is dissolved in nitric acid, and treated with an excess of cold caustic potash. If a precipitate is formed the filtrate is boiled, whereby chromium, if present, is precipitated; in the filtrate from the chromium, acetic acid in excess precipitates any phosphate of alumina; and from the filtrate from this, phosphate of soda precipitates the original alumina as a phosphate.

The precipitate got by adding cold caustic potash to the nitric acid solution of the original ammonia precipitate is redissolved in nitric acid, treated with tartaric acid, and then supersaturated with ammonia. If a precipitate (A) is formed, it is owing to the presence of the phosphates or oxalates of the alkaline earths. The precipitate is dissolved in nitric acid, and treated with protonitrate of mercury. A precipitate shows the presence of oxalic acid, which is separated from the mercury by digesting the oxalate of mercury with sulphide of ammonium, and filtering. The filtrate from the oxalate of mercury is saturated with ammonia, which precipitates the original phosphoric acid in combination with mercury; the two are separated by digestion with sulphide of ammonium, and filtration. The filtrate from the phosphate of mercury is examined for baryta, strontia, lime, and magnesia (which, if present, exist now as nitrates), according to the method described among the bases. The filtrate from precipitate A contains the phosphate of iron, and also the nitrate of the iron which was originally precipitated as an oxide. To a portion of this filtrate, acetic acid and then ferrocyanide of potassium are added; the formation of Prussian blue shows the presence of iron. To another portion chloride of ammonium and then sulphate of magnesia are added: the latter precipitates the phosphoric acid as a phosphate of magnesia and ammonia.

In order to test for the non-metallic elements when they are not present in the form of acids, they are in some cases separated by simple solvents, in others made to combine with oxygen, and the so-formed acids examined. Sometimes both methods are united. Free carbon and carbides are converted respectively into carbonic acid and carbonates on heating with oxide of copper. Free sulphur and phosphorus are soluble in bisulphide of carbon: the former is converted into sulphuric, the latter into phosphoric acid on boiling with nitric acid. Phosphides are decomposed by water or alkalis, phosphide of hydrogen being evolved. Compounds of nitrogen, as the nitrides, are decomposed by caustic alkalis, ammonia being evolved. The method of testing for the free gaseous elements is too obvious to need description.

Some salts resist the action of all solvents in the cold. Such are bin oxide of tin, sulphate of lead, sulphate of baryta. On fusing such bodies with carbonate of soda, their acids unite with the soda, and since all soda salts are soluble, they may be thus obtained in solution. Thus stannate and sulphate of soda would be formed from the above. The base, when such is present, combines with the carbonic acid, and the so-formed carbonate, after separation from the soluble soda salt of the acid, is dissolved in an appropriate acid.

Quantitative Analysis.—The methods used in determining the quantity of a constituent in a compound substance, are mainly based upon the experience that in all chemical compounds the constituents are united with one another in definite proportions. For it is a consequence of this fact, that if we can unite a constituent A of a compound with any other body B, so as to produce a substance, the definiteness and invariableness of whose composition is established; then, from the amount of the product AB, we may deduce the amount of the substance A contained in the original compound. Thus, if we wish to ascertain the quantity of hydrogen which a substance contains, our object is effected if we can succeed in combining the whole of the hydrogen with oxygen in such a manner as to form water, and in determining the amount of water so produced. Because, from the fact that water consists of eight parts by weight of oxygen to one of hydrogen, one-ninth of the weight of the water found, will be the weight of the hydrogen which the original substance contained. In other words, from the weight of a compound whose constituents are in definite proportions we know the weight of each of its constituents. Hence, in determining quantitatively the amount of a substance present, we have to seek to combine it in such a manner with some other substance, that the resulting compound may so differ in physical property (solubility or insolubility, volatility) from all other bodies present as to admit of perfect separation from them.

But it is also an immediate result of the definite nature of chemical

change, in respect to the quantities of the bodies concerned, that from the amount of substance B required to be added to a substance A, in order, only just, but perfectly to complete the chemical change, the quantity of A present may be deduced. As, in most cases of this species of determination, the reagents are used in solution of known strength, and the amounts of solution employed are determined by measure, this kind of quantitative analysis has received the name of Volumetric Analysis, or Analysis by Standard Solutions. (See VOLUMETRIC ANALYSIS.)

The separation of the constituents of a substance by precipitation is the method most frequently employed for their determination, and hence the collection and weighing of precipitates is an operation of very frequent occurrence, and of the greatest importance, in quantitative analysis.

It is evident that all the operations of quantitative analysis must be performed with the utmost nicety of manipulation with respect to cleanliness, avoidance of loss, and thoroughness.

The determination of the weight of a substance is performed on a balance of the most sensible kind,—a balance which will bear fifty grammes on each pan, and which will turn, when so loaded, when an additional milligramme is placed on one of the pans. The weights most usually employed are grammes and their decimal parts. Milligrammes are usually indicated, not by weights having this absolute value, but by placing a centigramme fashioned of wire at various distances from the fulcrum on one of the arms of the balance, which, for this purpose, is divided into tenths.

In general, when a substance which has been precipitated from a solution and collected on a filter is weighed, it is previously strongly ignited, in order to free it from all traces of adhering moisture; and since the solid substance cannot be separated from the filter without loss, the filter must be burned with the substance. The ash which the filter would leave on being burned alone is thus weighed with the substance estimated; it is necessary, therefore, to know the weight of such ash, and to deduct it from the weight found, in order to get the weight of the substance. On account of the smallness and constancy of its ash, Swedish filtering-paper is ordinarily employed: if a sheet of such paper, of known area, be burned and its ash weighed, the weight of the ash of a circular piece of known diameter can be easily reckoned.

The hypothetical analysis of a substance will give the best idea of the manipulatory processes generally employed. Let us suppose that we have to determine quantitatively the composition of crystallised sulphate of copper ($\text{CuSO}_4 + 5\text{H}_2\text{O}$); that is, to determine quantitatively (1) the water, (2) the sulphuric acid, and (3) the copper. A clean platinum crucible is heated to redness over a smokeless lamp; it is placed, by means of pliers tipped with platinum, while still hot, in a jar closed at the top with a well-fitting plate, and containing some strong sulphuric acid. The crucible is supported over the acid, on an iron triangular tripod, whose legs are cased in glass tubes closed at the bottom, and whose sides, on which the crucible rests, are coated with platinum foil. When the crucible is quite cold, it is weighed. Let its weight be C. About 1.5 grammes of sulphate of copper, which has been recrystallised, powdered very finely, and dried, to remove mechanically adhering water, by being pressed for some hours between folds of blotting-paper, is placed in the crucible, and the whole is weighed. If the new weight be C + S, then S is the weight of the sulphate of copper. The crucible, with the sulphate, is now kept for an hour at a temperature a little below redness. After cooling as before in the dry-air chamber, its weight is found to be C + S - W; then W is the weight of the water which has been driven off, and this is the whole of the water which was contained in the original sulphate.

The sulphate which has thus been deprived of water, but which has lost neither sulphuric acid nor copper, is now transferred without loss into a beaker glass containing distilled water, and the adhering particles of sulphate are washed out of the crucible into the beaker, whose contents are thereon heated to boiling, whereon the whole of the sulphate is dissolved. A clear solution of chloride of barium is gradually added, until fresh portions cause no further precipitation. When the sulphate of baryta so formed has subsided, the supernatant liquid is poured off upon a moistened filter of Swedish paper, and the whole of the filtrate is collected in another beaker. The sulphate of baryta is then washed out of the first beaker on to the filter. When as much liquid as possible has drained through, a stream of boiling distilled water is directed upon the sulphate of baryta from the wash-bottle previously described, until the filter-paper is filled to within about a quarter of an inch of the top; when this has run through, a fresh portion of water is added, and the same process is repeated six or eight times, the whole of the wash-water being collected in the second beaker. The washing is complete when a drop of the wash-water leaves no residue when evaporated on platinum foil. When thoroughly washed, the funnel containing the sulphate of baryta is covered with paper, and set apart in a warm place to dry. The filtrate contains chloride of copper along with the excess of chloride of barium used. The latter is removed by boiling, adding dilute sulphuric acid until further precipitation ceases, filtering and washing as before: the filtrate alone is preserved. The filtrate from the second precipitate of sulphate of baryta is collected in a silver basin, and evaporated at a temperature below its boiling point as it is being collected. When its bulk is reduced to two or three

liquid ounces, an excess of a solution of pure caustic potash is added, and the whole heated for a few minutes to boiling. The copper is thereby completely precipitated as black oxide; this is filtered from the sulphate of potash, and washed as before described. The filtrate need not be kept. The funnel is covered and dried as before.

The crucible, whose weight is C, is now placed upon a sheet of black glazed paper. The filter containing the sulphate of baryta is unfolded, and as much as possible of the sulphate shaken into the crucible. The sides of the paper are rubbed together to remove the adhering sulphate. The filter is folded up again, and, being so rolled together that all the edges are inside, it is wrapped in a piece of platinum wire, set on fire over the lamp, and held over the crucible. It is then held above the lamp until all incandescence has ceased, and perfect whiteness is attained; then being shaken into the crucible, into which all particles which have been spilled are swept from the paper by a feather, the whole is heated for half an hour to redness, allowed to get cold as before, and weighed. Its weight is C + A + M; so that M is the weight of the sulphate of baryta (BaOSO_3). From the equivalent of barium being 68.6, that of oxygen 8, and that of sulphur 16, we know that the equivalent of sulphate of baryta is 116.6.

$$\begin{array}{rcl} \text{Ba} & = & 68.6 \\ \text{O} & = & 8 \\ \text{S} & = & 16 \\ \text{O}_3 & = & 24 \\ \hline & & 116.6 \end{array}$$

That is, 116.6 parts by weight of sulphate of baryta contain 40 of SO_3 . Hence the amount of sulphuric acid found in the sulphate of baryta, that is, in the original sulphate of copper, is—

$$M \cdot \frac{40}{116.6} (= \Sigma)$$

The oxide of copper is ignited and weighed in the same manner. Let the crucible, filter ash, and oxide of copper, together weigh C + A + N, then N is the weight of the oxide of copper. We have thus found the absolute weights of the water, sulphuric acid, and oxide of copper, contained in a given weight of sulphate of copper. If the analysis has been performed with perfect accuracy, it is evident that the sum of these three quantities should be identical with the weight of the sulphate of copper taken. But in order to compare various analyses with one another in which different quantities of substance have been employed, it is convenient, from the absolute weights so found to deduce the amounts of the various constituents which would be contained in 100 parts, by weight; in other words, to find their per centage amount.

If S grammes contain W grammes of water, Σ of sulphuric acid, and N of oxide of copper, then 100 grammes will contain $W \frac{100}{S}$ of water, $\Sigma \frac{100}{S}$ of sulphuric acid, and $N \frac{100}{S}$ of oxide of copper, and the sum of these should, of course, be 100. In practice, however, this is very rarely the case. Inaccuracies in weighing, imperfect insolubility of precipitates, imperfect washing, inexact determination of equivalents, loss by manipulation, &c., are sources of error which it is impossible wholly to avoid. The exactness of an analysis, that is, the nearness to 100 to which the sum of its per centage constituents amounts, depends of course upon the nature and number of the substances to be determined; an error of two- or three-tenths per cent. in each is generally admissible.

It is impossible to describe fully the methods and precautions used in the quantitative determination of the various elements.

Potassium is estimated as KCl, PtCl_2 .

Sodium as NaCl, or NaO SO_3 .

Ammonium as NH_4Cl , PtCl_2 , or from the amount of platinum which this salt contains.

Lime as CaO CO_2 , derived from the gentle ignition of the insoluble oxalate.

Strontia as SrOSO_3 , which is insoluble in alcohol.

Baryta as BaO SO_3 .

Magnesia as 2MgO PO_5 derived from the ignition of the insoluble $2\text{MgO NH}_4\text{OPO}_5$.

Iron as Fe_2O_3
Aluminium as Al_2O_3
Chromium as Cr_2O_3
Manganese as Mn^{3+}O^4
Zinc as ZnO
Nickel as NiO
Cobalt as Co

Arsenic as AsS_3
Antimony as SbS_3
Tin as SnO_2
Gold
Platinum } as metals.
Mercury }
Lead as PbO SO_3
Silver as AgCl
Bismuth as BiO_3
Cadmium as CdO
Copper as CuO.

The acids are estimated—

Hydrochloric	} acids as	AgCl
Hydriodic		AgI
Hydrobromic		AgBr
Hydrocyanic		AgCy

Carbonic acid by the loss in weight experienced on its expulsion.

Sulphuric as BaOSO_3 .

Hydrosulphuric by conversion into sulphuric, as BaOSO_3 , or as AsS_3 .

Boracic as BoO_3 .

Silicic as SiO_3 .

Phosphoric as 2MgO PO_5 , derived from the ignition of the insoluble $2\text{MgO NH}_4\text{OPO}_5$.

Oxalic from the amount of CaOCO₂, found on igniting the insoluble CaO C₂O₃.

Chloric from the amount of chloride formed on igniting its salts.

Nitric from the quantity of Cu it dissolves in the presence of hydrochloric acid.

Sometimes one of two substances which are nearly allied and which occur together, is estimated by deficiency. Thus, if we have a weighed quantity of the mixed chlorides of sodium and potassium, the chloride of potassium contained in the mixture is determined by estimating the amount of KCl, PtCl_2 to which it gives rise, the amount of chloride of sodium is the difference between the weight of the mixed chlorides and that of the chloride of potassium. Or again, if we have a mixed chloride and iodide of potassium, the two halogens are combined with silver, and a weighed quantity of the mixed silver salts being taken, is subjected to the action of a stream of dry chlorine. The chlorine replaces the iodine, and the loss experienced thereby in weight is the difference between the iodine which has been driven out and the chlorine which has entered. The quantity of iodine, and hence that of chlorine, may be thence easily calculated.

CHEMICAL COMBINATION. [CHEMICAL AFFINITIES.]

CHEMICAL EQUIVALENTS. The term chemical equivalent is frequently used as synonymous with the expressions *atomic weight* and *combining proportion*; strictly, however, it is by no means synonymous with these terms; since the equivalent of a body may be, and occasionally is, different from its atomic weight or combining proportion. An equivalent of a substance obviously means such a weight or volume of that substance as is required to replace another body in a definite chemical compound. Thus if we take the element hydrogen and combine it with iodine, we find that 1 lb. of hydrogen combines with exactly 126.88 lbs. of iodine. Now if the hydriodic acid thus formed be brought into contact with a sufficient quantity of bromine, the iodine will be expelled and its place occupied by the bromine, of which exactly 79.97 lbs. will have taken the place of the 126.88 lbs. of iodine. The bromine compound may in like manner be decomposed by chlorine, and it is found that only 35.49 lbs. of chlorine are required to replace or expel the 79.97 lbs. of bromine. Finally, oxygen may be made to replace the chlorine when 8 lbs. of oxygen are found to be capable of expelling the whole of the chlorine. It is therefore obvious that 126.88 lbs. of iodine, 79.97 lbs. of bromine, 35.49 lbs. of chlorine, and 8 lbs. of oxygen, are equivalent to each other in chemical combination, but a reference to the table of atomic weights [ATOMIC THEORY], shows that these numbers are also the atomic weights of the respective elements. If, however, we now replace the oxygen contained in the compound last mentioned, with nitrogen, phosphorus, arsenic, or antimony, we find that the weights of these elements required to replace the 8 lbs. of oxygen are respectively 4.7, 10.7, 25, and 43, numbers which do not coincide with the atomic weights or combining proportions of these elements, but which are exactly one-third of those weights. In other words, in these cases the atomic weight of the element is made equal to three times its equivalent number, and we formulate the last-mentioned compounds as follows:—

Ammonia	• • • • •	NH_3
Phosphuretted hydrogen	• • • • •	PH_3
Arsenuretted hydrogen	• • • • •	AsH_3
Antimonuretted hydrogen	• • • • •	SbH_3

The reasons for departing from the general rule in these cases may be thus stated, in the case of nitrogen, and many of them apply also with equal force to the other elements in question:—

1. Because it is found that a given bulk of gaseous ammonia contains three times as much hydrogen as the same bulk of hydrochloric acid (HCl).

2. Because it is found that a given bulk of nitrogen combines with three times as much hydrogen as does the same bulk of chlorine; and that the relative weights of equal bulks of nitrogen, chlorine, and hydrogen are as 14 : 35.49 : 1.

3. Because certain undoubted analogies are concealed if the combining proportion of nitrogen be taken as 4.7, whilst they are rendered evident if the number 14 be adopted.

4. Because in nearly every case the quantity of ammonia which is the agent or resultant of a reaction, contains three atoms of hydrogen or some multiple of three atoms of hydrogen; and consequently fourteen, or some multiple of fourteen parts of nitrogen.

5. Because, in ammonia, the replacement of hydrogen by other bodies takes place definitely in thirds by three successive stages.

6. Because the formulæ of the compounds of nitrogen with oxygen, would be abnormal and without all analogy if the atomic weight of nitrogen were taken at 4.7 whereas the number 14 gives formulæ which, on account of the regular gradations which they exhibit, cause the compounds of nitrogen and oxygen to be very generally selected as illustrations of the law of multiple proportions.

A similar train of reasoning has recently been very ingeniously applied by Williamson, Brodie, and Odling, to carbon, oxygen, sulphur, and some other elements, the atomic weight of which ought, according to these chemists, to be doubled. In the case of carbon this might probably be done with advantage; but the doubling of the atomic weight of oxygen, although it would allow certain classes of organic compounds to be represented by somewhat more simple formulæ, would yet add considerably to the complexity of others. Although these views have not yet been generally adopted, they have received the assent of several of the most eminent chemists. For further details on this subject see an excellent paper by Dr. Odling in the 'Quarterly Journal of the Chemical Society,' vol. xi. p. 107. [ATOMIC THEORY.]

CHEMICAL FORMULÆ. The use of symbols in chemistry to represent elements has given rise to the use of groups of symbols to represent groups of elements. Such groups of symbols are formulæ. Formerly the metals which were then known were represented by the zodiacal signs of the sun and planets; and shortly after the isolation of the great bulk of the non-metallic elements, arbitrary symbols were invented for their representation, and formulæ were constructed by the juxtaposition of these symbols. The clumsiness, for this purpose, of the zodiacal signs, and of those subsequently proposed, has prevented their use. The symbol adopted universally, at present, for an element is the first letter of its Latin name, in those cases where it has been named in the Latin tongue. If, as is the case with most elements, its discovery is of later date, the first letter of the name given to it is employed for its symbol. But, as there are about sixty elements, and only twenty-six letters in the European alphabet, the names of some elements must necessarily commence with the same letter. To obviate the ambiguity which naturally results from this, the symbols of the less important of the elements beginning with the same letter are compounded of the initial letter and some other letter in their names. The first (or only) letter is always written of the capital size, the second is written small.

In a few instances, different names are given to the same element by the Germans, French, and English, and consequently different symbols are used in the three countries. Thus, the French name for nitrogen is azote, and its symbol in that country is Az. The metal which the English call bismuth is called in Germany wismuth, and its symbol is there Wi. The Germans call tungsten, wolfram; and both they and the English symbolise it by W, &c. Fortunately, however, these are almost the only instances where such dissimilarity exists.

In a few instances compound bodies have received special symbols, as well as those built up from the symbols for the elements of which such compounds are formed. The following table shows all the elements which are at present definitely known, with their symbols.

Aluminium . . .	Al	Nitrogen . . .	N
Antimony . . .	Sb	Osmium . . .	Os
Arsenic . . .	As	Oxygen . . .	O
Barium . . .	Ba	Palladium . . .	Pd
Bismuth . . .	Bi	Pelopium . . .	Pl
Boron . . .	Bo	Phosphorus . . .	P
Bromine . . .	Br	Platinum . . .	Pt
Cadmium . . .	Cd	Potassium . . .	K
Calcium . . .	Ca	Rhodium . . .	R
Carbon . . .	C	Ruthenium . . .	Ru
Chlorine . . .	Cl	Selenium . . .	Se
Chromium . . .	Cr	Silicon . . .	Si
Cobalt . . .	Co	Silver . . .	Ag
Copper . . .	Cu	Sodium . . .	Na
Didymium . . .	Di	Strontium . . .	Sr
Erbium . . .	Er	Sulphur . . .	S
Fluorine . . .	Fl	Tantalum . . .	Ta
Glucinum . . .	Gl	Tellurium . . .	Te
Gold . . .	Au	Terbium . . .	Tr
Hydrogen . . .	H	Tin . . .	Sn
Iodine . . .	I	Titanium . . .	Ti
Iridium . . .	Ir	Thorium . . .	Th
Iron . . .	Fe	Tungsten . . .	W
Lanthanum . . .	La	Uranium . . .	U
Lead . . .	Pb	Vanadium . . .	V
Lithium . . .	Li	Yttrium . . .	Y
Magnesium . . .	Mg	Zinc . . .	Zn
Manganese . . .	Mn	Zirconium . . .	Z
Mercury . . .	Hg	Water . . .	Aq
Molybdenum . . .	Mo	Oxalic acid . . .	O
Nickel . . .	Ni	Tartaric acid . . .	T
Niobium . . .	No		

One of these symbols, therefore, used alone, denotes an indefinite amount of the element which it represents. But as a consequence of the law of definite chemical combination, when more than one element is present in a chemical compound a more precise meaning attaches itself to such a symbol. It signifies, in such case, one atom or combining proportion of the element. [See ATOMIC THEORY and CHEMICAL EQUIVALENTS.] Thus CO denotes six parts of carbon combined with eight of oxygen, and is consequently the formula of carbonic oxide. When more than one equivalent of an element is in chemical combination, the number of equivalents or atoms is attached above or below to the symbol representing the element. So that CO₂ or CO² is the formula for carbonic acid, which contains six parts of carbon to sixteen of oxygen.

A chemical formula of a compound body, which merely gives the elements present and their total respective quantities, is said to be an irrational or *empirical formula*. In many compound bodies, evidence, either analytical or synthetical, points to the existence of a closer union between certain elements or groups of elements than obtains between others. A chemical formula which expresses this more or less thoroughly is more or less a *rational formula*. The purpose of a rational formula, therefore, is to represent the structure of a compound, or the grouping of the elements of which it is composed. The most intimate union of two elements, or two groups of elements, is expressed by the simple juxtaposition of their symbols or formulæ (KCl, chloride of potassium). In cases of less intimate union, a comma is introduced (NH₄Cl, PtCl₂, bichloride of platinum ammonium). When two elements or groups are still more loosely combined, they are connected by the plus sign, + (CuOSO₃ + 5HO, penthydrated sulphate of copper). When several molecules or groups of elements are concerned, the number of such molecules is represented either by embracing the group in brackets and attaching the number to the bracket, or by placing the number before the group, in which latter case the number is a factor of all the symbols after it as far as the next sign (, or +) of less intimate combination, Fe₂O₃(SO₃)₃ Persulphate of iron, or Fe₂O₃3SO₃.

An example will illustrate this.

Aluminium combines with oxygen in the proportion of two atoms of aluminium to three of oxygen, Al₂O₃ (alumina).

Sulphur combines with oxygen in the proportion of one atom of sulphur to three of oxygen, SO₃ (anhydrous sulphuric acid).

Alumina combines with anhydrous sulphuric acid in the proportion of one molecule of alumina to three molecules of sulphuric acid, Al₂O₃3SO₃ (sulphate of alumina).

Again, potassium combines with oxygen in the proportion of one atom of potassium to one of oxygen, KO (potash).

Potash combines with anhydrous sulphuric acid in the proportion of one molecule of potash to one molecule of sulphuric acid, KOSO₃ (sulphate of potash).

Further, sulphate of alumina combines with sulphate of potash, in the presence of water, in the proportion of one molecule of the sulphate of alumina to one molecule of sulphate of potash, KOSO₃, Al₂O₃3SO₃; and finally, this latter compound salt combines with water in the proportion of one molecule of the compound salt to twenty-four molecules of water, KOSO₃, Al₂O₃3SO₃ + 24HO (crystallised potash alumina alum). The above is an instance of the representation by a rational formula of the structure of a compound as derived from its synthesis. The empirical formula of the same body would be KAl₂S₄H₂₄O₄₀.

Again, if we take borax and heat it, we find that a certain quantity of water is given off. The residue remains so far unchanged that it dissolves in and crystallises with water, giving rise to the original substance. We conclude hence that—

Σ , on being treated with sulphuric acid, gives rise to sulphate of soda NaOSO₃, and another body, Σ_1 , whence

If the substance Σ_1 be heated with sodium, soda NaO is formed, and a new body, Σ_2 , appears as a black powder; hence

Σ_2 refuses to be further decomposed; it is therefore an element, and is called Boron. Consequently, borax consists of oxide of sodium and oxide of boron. For the determination of the numbers n, m, and p in the above equations, the reader is referred to the articles ATOMIC THEORY and CHEMICAL EQUIVALENT. The rational formula for borax is

It must, however, be borne well in mind, that all rational formulæ are partial, inasmuch as they cannot express the whole of the molecular arrangements of the bodies to which they refer; and arbitrary, because they cannot but give undue prominence to particular theoretical views and tendencies. A compound body may be divided into different proximate constituents, according to the different substances which act upon it, and according to the different physical conditions which accompany such action; and one and the same body may be constructed synthetically from different groups of elements. Thus, alcohol, when heated to a certain temperature with strong sulphuric acid, gives up water, being converted into ether. Hence it may be viewed as the ethylate of water—

But at a higher temperature sulphuric acid transforms alcohol into olefiant gas, or ethylene, depriving it thereby of twice as much water as it did in converting it into ether: whence alcohol may be viewed as olefiant gas and water—

Or, synthetically, alcohol may be formed either by acting upon chloride of ethyl with hydrated potash,

or, by dissolving olefiant gas in sulphuric acid, and decomposing the compound with water—

Certain bodies, which differ widely from one another in their physical properties, may be composed of the same elements in the same proportion. Thus, all the olefines, ethylene, propylene, butylene, &c., consist of 85.71 *per cent.* of carbon and 14.29 *per cent.* of hydrogen. These bodies differ physically as to their densities, as liquids and gases, and as to the temperature at which they pass from the one state into the other. They all combine directly with bromine, and give rise thereby to products having complete chemical analogy with one another. The body thus formed by the union of ethylene with bromine contains for every two atoms of bromine four of carbon and four of hydrogen. The corresponding product from propylene contains six of carbon and six of hydrogen for every two of bromine; that from butylene contains eight of carbon and hydrogen for two of bromine, &c. Whence the formulæ of the bodies are respectively

and, consequently, the formulæ of the olefines themselves are—

Ethylene	.	.	.	.	.	.	.	C_4H_4
Propylene	.	.	.	.	.	.	.	C_6H_6
Butylene	.	.	.	.	.	.	.	C_8H_8
Amylene	.	.	.	.	.	.	.	$\text{C}_{10}\text{H}_{10}$

Moreover, it is found that the specific gravities of these olefines, in the state of gas or vapour, at the same pressure and temperature, are respectively—

Ethylene	.	.	.	.	.	.	.	9784
Propylene	.	.	.	.	.	.	.	1.467
Butylene	.	.	.	.	.	.	.	1.926
Amylene	.	.	.	.	.	.	.	2.68

numbers nearly in the proportion of 4, 6, 8, 10, respectively, showing that in the same volume of the different vapours, the atoms of the two elements are present in numbers proportional to the above. It is thus that the specific gravity of a substance in the gaseous state,—that is, its vapour density,—shows how many atoms (relatively) it contains, and gives thus so far evidence of its rational formula. For the relation between the rational formula of a body and its specific gravity, when in the solid or liquid state, the reader is referred to ATOMIC VOLUME.

CHEMICAL NOMENCLATURE. The experiments of the early chemists soon increased the number of distinct substances to such an extent, as to render at least a crude nomenclature indispensable, in order to define new bodies in such a manner as to enable subsequent experimenters to recognise them and to apprehend something of their nature. Thus, to indicate the analogies which existed between different sulphates, they designated them by the name of *vitriols*; for a similar reason they gave the names *horn silver*, *horn lead*, &c., and *butter of antimony*, *butter of bismuth*, *butter of zinc*, to compounds of chlorine with certain metals: these names indicating the resemblance in appearance which the first bore to horn and the second to butter.

The names of the simple elements have been formed on no definite plan; they have been given according to the choice of their first discoverer, or of the chemist who first described their properties. Many of them, as antimony, strontium, barium, potassium, aluminium, have received their names from substances in which they existed as characteristic constituents, and which were so named before any certain knowledge of their composition existed. On the introduction of the present system of nomenclature, an attempt was made to give to the elements names characteristic of their properties. This idea it was found impossible to carry out systematically; some of the commonest names had been so engrafted in the science that it was found impossible to root them out. Whole classes of the elements, too, have so little that is characteristic, that it would be difficult to find adequately descriptive names. Further, in framing a systematic nomenclature, it is impossible to avoid giving it the impress of the theoretical ideas prevailing at the time. These names become subsequently modified, from the progress of the science and the discovery of new bodies. Hence, a nomenclature, quite rational at its birth, ceases, after some time, to be in harmony with the state of the science. Many of the names given to the elements at the time of the foundation of our present nomenclature, were in accordance with the theoretical views prevailing at the time, and have been found by the further progress of the science to be inappropriate. Thus oxygen, discovered about that time, was named from *οξύς*, acid, and *γεννέω*, to generate, because it was conceived to be the acidifying principle; the subsequent recognition of the non-existence of oxygen in bodies endowed with highly acid properties, and the existence of oxygen in strictly basic compounds, showed the inappropriateness of the name. For the names of the elements, see CHEMICAL FORMULÆ.

Simple bodies are divided into *metalloids* and *metals*. This classification was based, at first, principally on physical characteristics; but the best distinction is that founded on their chemical properties, namely, that metalloids, in uniting with oxygen, generally form acid compounds, whilst metals, in combining with oxygen, generally give rise to bases.

Every binary compound, or compound of two elements, which can be rendered liquid and a conductor of the electric current, is decomposed by the action of a sufficiently powerful battery; one of its elements is attracted to the positive pole, and the other to the negative pole. As opposite electricities attract each other, the *electro-negative body*, or acid element, is that which goes to the positive pole; and the *electro-positive body*, or basic element, is that which goes to the negative pole. The metalloids are consequently, as a general rule, electro-negative bodies, and the metals electro-positive bodies.

To name a binary compound, we enunciate first the name of the electro-negative body, giving to it the termination *ide* or *uret*, and follow it by the genitive case of the name of the electro-positive body: thus, oxide of silver, sulphuret of mercury.

Of binary compounds, by far the most important are those which the elements form with oxygen. They afford the best examples of the principles on which nomenclature is applied. From their properties they may be divided into acids and bases.

Nomenclature of acids. The names of acids are obtained by affixing to the names of the elements, or some abbreviation of those names, the termination *ic*. Thus the combinations of sulphur and of titanium with oxygen are respectively sulphuric and titanitic acids. Where an element combines in more proportions than one with oxygen to form an acid, the termination *ous* is applied to that which contains least oxygen: thus we have *sulphurous acid* and *sulphuric acid*. At the time when these rules were established, it was thought that a body could not form with oxygen more than two acid compounds; but subsequently cases were discovered in which the body formed four or five combinations with oxygen. These cases were provided for by the use of the Greek prefixes *υπο* (under) and *υπερ* (above). Thus an acid containing less oxygen than sulphurous acid was called *hyposulphurous acid*, and an acid between sulphurous and sulphuric acid was called *hyposulphuric acid*. In the series of acids which chlorine forms with oxygen, we have *hypochlorous acid* (ClO), *chlorous acid* (ClO_2), *hypochloric acid* (ClO_3), and *chloric acid* (ClO_4); on the discovery of an acid (ClO_7) containing more oxygen than chloric acid, it was termed *hyperchloric*, or briefly, *perchloric acid*. There are, similarly, *periodic* and *permanganic acids*. A class of bodies exists which have acid properties, but in which sulphur is contained in the place of oxygen; thus, AsS_5 , AsS_3 , CS_2 , which are termed respectively, *sulpharsenic*, *sulpharsenious*, and *sulphocarbonic acids*. Certain elements, as chlorine, sulphur, iodine, form acid compounds with hydrogen. These are respectively termed *hydrochloric*, *hydrosulphuric*, and *hydriodic acids*.

Nomenclature of Bases.—The compounds of metals with oxygen are generally bases. In accordance with the principle of nomenclature before stated, they are termed *oxides*. In certain cases, metals combine with several proportions of oxygen; these combinations are always in simple ratios, and according to the law of multiple proportions. To the one containing an atom of oxygen for an atom of metal, the term *protoxide* (*πρωτος*, first), or simply *oxide* is applied; and to the others, the terms *sesquioxide*, *binoxide*, *teroxide*, according as they contain $1\frac{1}{2}$, 2, or 3 times as much oxygen as is contained in the protoxide. Thus we have MnO , protoxide; Mn_2O_3 , sesquioxide; and MnO_2 , binoxide of manganese. A similar nomenclature obtains with higher oxides, but these have generally acid properties. For instance, manganese combines with three atoms of oxygen to form a compound (MnO_3) which is termed *manganic acid*. It also combines, in the proportion of 2 equivalents of manganese to 7 of oxygen, to form an acid which is termed *permanganic acid*. The term *peroxide* is frequently applied to that oxygen compound which contains most oxygen, if it be not an acid; thus we say indifferently sesquioxide and peroxide of iron.

Certain oxides exist containing less oxygen than the protoxides. These are termed *suboxides*: as Cu_2O , suboxide of copper; Pb_2O , suboxide of lead. They are generally not very stable compounds.

The combinations of the other elements are similarly named. The combinations of sulphur, phosphorus, chlorine, carbon, and nitrogen with other elements are termed respectively sulphides, phosphides, chlorides, carbides, and nitrides. The termination *uret* is becoming gradually replaced by *ide*.

Where several combinations of the same elements exist, the same rules are applied as in the case of the oxides. Thus, protochloride of iron, FeCl , and sesquichloride of iron, Fe_2Cl_3 ; protochloride of tin, SnCl , and bichloride of tin, SnCl_2 ; terchloride of antimony, SnCl_3 , and pentachloride of antimony, SbCl_5 .

In the series of combinations which sulphur forms with phosphorus, we have the hemisulphide, P_2S ; monosulphide, PS ; tersulphide, PS_3 ; pentasulphide, PS_5 ; and dodecosulphide, PS_{12} . We have also iodide of copper, CuI ; and subiodide of copper, Cu_2I .

Nomenclature of Salts. Acids in combining with bases give rise to ternary compounds which are called salts. To form their names those of the acid and base are combined, so that the name of the first determines the kind, and of the latter the species; the termination *ic* and *ous* of the acid being respectively changed into *ate* and *ite*. Thus, we should say *sulphate of protoxide of iron*, *sulphite of protoxide of iron*, *hyposulphate of protoxide of iron*, to express the combinations of sulphurous, sulphuric, and hyposulphuric acid, respectively, with oxide of iron; or the existence of oxygen in the base being supposed, we may say *sulphate of iron*, *sulphite of iron*, *hyposulphate of iron*.

In cases in which an acid—for example, sulphuric acid—combines

with a sesquioxide as well as with a protoxide of the metal, as is the case with iron, the salts are called respectively *sulphate of protoxide*, and *sulphate of peroxide of iron*; or, more briefly, *protosulphate* and *persulphate of iron*. These two oxides of iron are termed respectively *ferrous* and *ferric oxide*, and these salts it has been proposed to term *ferrous* and *ferric sulphate*. This mode of nomenclature has much that is advantageous, and has been extended to several other cases; thus, the terms *mercurous nitrate*, and *mercuric nitrate*, express respectively the nitrate of protoxide of mercury, and the nitrate of peroxide of mercury.

Where an acid combines with a base in more proportions than one, the principles heretofore described obtain. We have thus *sulphate* and *bisulphate of potash*, to express the combination of 1 and 2 equivalents of sulphuric acid respectively with the base potash; *Oxalate*, *binoxalate*, and *quadroxalate of potash*, to express respectively the combinations of 1, 2, and 4 equivalents of oxalic acid with 1 equivalent of potash. *Sesquicarbonate of soda* signifies a combination of $1\frac{1}{2}$ equivalents of carbonic acid with 1 equivalent of soda.

Salts containing more base than exists in the neutral salt are termed *basic salts* or *subsals*. We have *acetate of lead*, and *subacetate of lead*; *sulphate of iron*, and *tribasic sulphate of iron*: the latter expressing a proportion of base three times that which exists in the neutral salt.

Combinations of water with acids or with bases are termed *hydrates*; thus, *hydrate of potash* (KOH), *hydrated boracic acid* (BO₃H₃O).

Double salts are expressed by the names of the salts of which they consist: the name of the common acid not being repeated. *Sulphate of copper and potash* expresses the combination of sulphate of copper with sulphate of potash; *chloride of platinum and potassium* (KCl, PtCl₂) expresses the combination of chloride of platinum with chloride of potassium. Some chemists regard the chloride of platinum as playing the part of an acid, and the above compound is frequently termed *platinochloride of potassium*.

In the present state of organic chemistry, in which new substances and new processes are being discovered daily, it would be impossible to propose any system of nomenclature which could at all claim to be permanent. The difficulties are further enhanced by the great difference of opinion which prevails among chemists as to the constitution of organic compounds. Bodies which have been studied by different chemists, and which admit of being regarded from different points of view, frequently possess several names. Thus, chloroform, C₂HCl₃, may receive different names according as we view it, as C₂H'''Cl₃, the

chloride of the tribasic radical *formyl*, C₂H''', or as being C₂ $\left\{ \begin{array}{c} \text{H} \\ \text{Cl} \\ \text{Cl} \\ \text{Cl} \end{array} \right\}$

marsh gas (C₂H₄), in which 3 equivalents of hydrogen are replaced by 3 equivalents of chlorine. The nomenclature of organic compounds hence bears, to a certain extent, the impress of the state of transition; and, under these circumstances, it would be impossible in this brief space to do more than briefly indicate, in the most general manner, the application of the principles of nomenclature in certain special important families.

Certain groups of organic compounds, generally consisting of carbon and hydrogen, have the property of entering into combination with elementary bodies, as if they were themselves elements. The names of these compound radicals, as they are termed, are formed by affixing to some name which denotes their origin the termination *yl* (υλη, matter): as, for instance *ethyl*, the radical of ether; *amyl*, the radical of amyl alcohol; *acetyl*, the radical of acetic acid; *benzoyl*, the radical of benzoic acid. The termination *yl* is indifferently used, whether the radical contains oxygen or not.

The compounds of radicals with other substances are named on the same principles as are applied in the case of organic compounds. For example, *chloride of methyl*, *sulphide of ethyl*, *nitrate of amyl*, *hydride of benzoyl*, *selenium-ethyl*, *zinc-methyl*, &c.

Certain radicals, which have an electro-negative deportment, such as cyanogen, mellon, &c., give to their combinations the termination *ide*, as *cyanide of ethyl*, *mellonide of potassium*, &c.

The termination *al* is frequently employed to express the names of bodies which are either homologous with aldehyde or are derived from it. Thus: *butyral*, *valeral*, *chloral*, *bromal*, &c.

The termination *ole* is applied to certain neutral carbo-hydrogens. Ex.: *benzole*, *cumole*, *cymole*, &c.

The termination *ine* has been applied to substances of the most heterogeneous nature. Thus we have *haematine*, a constituent of the blood corpuscles; *stearine*, the combination of stearic acid with glycerine; *fibrine*; *inuline*, a modification of starch; *naphthaline*; *salicine*, &c. The terminal *e* is, however, now generally omitted from all such bodies when they do not possess qualities and composition analogous to ammonia.

The termination *ine* has been generally applied to the natural alkaloids extracted from substances of vegetable origin, such as *quinine*, *atropine*, &c. On the discovery of compounds possessing the closest analogies with these natural alkaloids, the same termination was assigned to them, as *aniline*, *cyanethine*, *thialdine*, &c.

A very large number of compounds have been discovered which resemble ammonia, and have hence been called *amide bases*, or *amines*. Viewed as ammonia, in which hydrogen is replaced by certain radicals,

they have received a corresponding nomenclature. A compound,

NC₂H₇, is ammonia $\left(\text{N} \left\{ \begin{array}{c} \text{H} \\ \text{H} \\ \text{H} \end{array} \right\} \right)$, in which hydrogen is replaced by

ethyl (C₂H₅), and is called *ethylamine*. An ammonia in which hydrogen is replaced by phenyl is called *phenylamine*. The name *bimethylamine*, or *dimethylamine*, is assigned to an ammonia in which 2 eq. of hydrogen are replaced by 2 of methyl (C₂H₃); *ethylphenylamine*, to an ammonia in which 2 eq. of hydrogen are replaced respectively by ethyl and by phenyl; *ethylmethylphenylamine*, to an ammonia in which 3 eq. of hydrogen are replaced respectively by ethyl, methyl, and phenyl.

Certain compounds have a composition analogous to the ammonium salts, and have received corresponding names. Thus, C₂₅H₂₄NCl =

$\left. \begin{array}{l} \text{C}_{12}\text{H}_5 \\ \text{C}_2\text{H}_3 \\ \text{C}_4\text{H}_5 \\ \text{C}_{10}\text{H}_{11} \end{array} \right\} \text{NCl}$ corresponds to chloride of ammonium, and is termed

chloride of *ethylmethylamylophenylammonium*. Such names are exceedingly unwieldy, but they possess the advantage of indicating the exact composition of the compounds to which they are applied.

In certain natural bases, hydrogen can be replaced by radicals, either simple or compound. Thus there are *chlorocinchonine*, *methyle*, *strychnine*, &c.

A large class of organic substances is formed by the substitution of hydrogen by an equivalent quantity of chlorine, bromine, hyponitrous acid, &c. Such compounds are called *substitution products*, and the principles on which they are named is evident from the following examples: *bichlorobutyric acid* (C₄H₆Cl₂O₄); *bromobenzole* (C₁₂H₅Br); *nitrobenzoic acid* (C₁₄H₅(NO₂)O₄); *binitrobenzoic acid* (C₁₄H₄(NO₂)₂O₄); *chloromiline* (C₁₂H₆ClN); *trichloroacetic acid* (C₄H₃Cl₃O₄), &c.

CHEMISTRY, from *χημεία* (*chemeia*). According to Suidas (in voc. *χημεία*) it was "the making of silver and gold," or what is now more generally known by the name of alchemy. [ALCHEMY.] Suidas adds that Diocletian burnt all the ancient books of the Egyptians on chemistry (as above explained), in order that the Egyptians might no longer be able to acquire wealth by the practice of this art, and thus be encouraged to resist the Romans. We may probably infer from this that *chemeia* is an Egyptian word; and if so, its resemblance to *Cham* or *Chem*, the genuine name of the country, is a confirmation of this supposition as to its origin. But whatever may have been the original meaning of the word, it no longer includes the imaginary process above-mentioned. Various definitions of its present meaning have been given. Gmelin defines chemistry as the science which treats of the combination of dissimilar bodies into homogeneous masses, and of the separation of dissimilar bodies from homogeneous masses. According to Thomson, "the object of chemistry is to determine the constituents of bodies, and the laws which regulate the combinations and separations of the elementary particles of matter."—*Inorganic Chemistry*, vol. i. p. 1.

The materials composing our globe, when brought into contact under favourable circumstances, are capable of undergoing certain changes, by which their physical properties become modified or entirely altered. The observation of these changes, the discovery and study of the laws which govern them, and the forces or conditions which modify, promote, or retard them, constitute the science of chemistry.

From the very nature of the operations in which man is compelled to engage for his own sustenance, comfort, and defence, as well as from the multitude of changes of the nature just mentioned, which are constantly occurring at the surface of our earth, it is evident that even the most ancient races could not be wholly ignorant of chemical phenomena, although the classification of these phenomena, and the deduction of the laws regulating and governing them, have been almost entirely the work of the past and the present century.

The science of chemistry cannot boast of any noble origin: on the contrary, it sprang from delusion and superstition, and was fostered by deception and credulity; hence its early history presents us with little that is truly interesting, sublime, or admirable. Many attempts have been made to trace the origin of chemistry to Tubal Cain, who, as an instructor of every artificer in brass and iron, is supposed to have had a considerable amount of chemical and metallurgical knowledge. Others attribute it to Hermes Trismegistus, whose son, Mizraim, was said to have first colonised Egypt, and though such statements may call a smile to the lips of those deeply versed in ancient lore and modern archaeological research, yet, involved as is the early history of this science in dark obscurity, the Sacred Writings, as well as the relics of the wonderful race that once peopled Egypt, bear strong testimony that they were acquainted with many chemical processes, which they employed for the preparation of colouring matters for their pottery, and in the embalming of their dead. The coloured glass beads with which their mummies are frequently decorated show also that they were not strangers to the art of glass-making. These, and other instances which might be mentioned, do not, however, allow us to conclude that chemistry was known and cultivated at this remote period as a science; on the contrary, its applications were probably only accidental and isolated, being practised by the various workmen empirically, and without any knowledge of the peculiar forces upon which the processes depended. By degrees, however, as

the number of observations increased, and various singular changes and transmutations were effected by the contact of different substances, the complete alteration in physical properties produced by chemical action attracted attention, and no doubt first led to the belief that all forms of matter were mutually convertible into each other, and hence that iron, lead, tin, copper, &c., could be transmuted into gold.

Whether this idea originated with the Egyptian Greeks or the Arabians is uncertain; but its promulgation attracted a host of adventurers to the prosecution of chemical experiments, who, instead of being disheartened by the continual failure of their processes, seemed only to be incited to greater activity by the difficulties met with in the solution of this important problem, which will probably never be proved to be an impossible one. The origin of experimental chemistry cannot be referred to a more remote period than the seventh or eighth century of the Christian era, and the early nomenclature seems to indicate that the Arabians were the most active in its prosecution; for instance, the words alcohol, aludel, alembic, and alcali, are evidently Arabic.

The history of the middle ages furnishes us with many narrations about the transmutations of metals, and the processes and manipulations by which the impostors or dupes pretended to perform them. The alchemists—as these men were called—had three principal objects of pursuit, namely, the philosopher's stone, possessing the property of transforming the baser metals into gold, the universal elixir to cure all diseases and confer immortality, and the universal solvent. The first of these objects was the most eagerly sought after, and it appears almost incredible to us, how large a number of persons became the dupes of the impostors professing to be possessed of the golden secret, since the mere fact of demanding remuneration for its disclosure, by the men who could produce gold in any quantity at pleasure, was a sufficient proof of the dishonesty of their pretensions. Contemporary with these impostors there lived, however, a large number of honest inquirers, who, although stimulated in their researches by a love of gain, were yet conscientious in their experiments and indefatigable in their exertions; to these men the science is incalculably indebted for the accumulation of an immense number of facts, which being isolated, and at that time comparatively uninteresting, would probably have long remained unknown, had not the golden dream of alchemy lent a charm to research, and stimulated these pioneers in the prosecution of their laborious and frequently dangerous experiments.

Though the new substances procured were at first thrown aside, as unworthy of attention, by the disciples of alchemy, yet the methods of preparation were generally preserved, and soon many of them began to receive important applications in medicine and the arts. Thus the importance of chemical inquiry and experiment, *per se*, began to be appreciated, and at the commencement of the seventh century, men of talent and ability devoted themselves to the study of these curious transformations and interesting phenomena. To Lord Bacon, however, chemistry is largely indebted, for perfectly freeing it from the trammels of alchemy which still pertinaciously hung upon it, hindering its development and stunting its growth: he happily described the alchemists as similar to those husbandmen who, in searching for a treasure supposed to be hidden in their land, by turning up and pulverising the soil, rendered it fertile, in seeking for brilliant impossibilities, they sometimes discovered useful realities; and referring to the chemistry of his time, he says, a new philosophy has arisen from the furnaces, which has confounded all the reasoning of the ancients. He first pointed out the value of experiment and observation over the unassisted human powers, and founded a new system of philosophical inquiry, by showing how little could be effected in the interpretation of natural phenomena, even by the strongest intellects, when unassisted by experimental research. Man, as the servant and interpreter of nature, can only discover her sublime truths by close observation and imitation of her operations.

The knowledge possessed of this science before the time of Constantine has been thus summed up by Bergman: "Some general idea may be formed of the state of chemistry in those days, from the consideration of the several subjects of the art with which they seem to have had no acquaintance. Except the acetic, no trace can be discovered of any other acid. The mineral alkali (carbonate of soda) was known to them by the name of nitre; but of the vegetable alkali (potash) they knew little; of the volatile (ammonia) they were altogether ignorant. Of neutral salts they had the marine (common salt), and the ammoniac (chloride of ammonium). Of earthy salts, they had native alum only; and of metallic salts, blue copperas and native green vitriol."

Of earths, they seem to have distinguished the calcareous and argillaceous; and of stones, a very considerable number.

Of inflammable substances, they were acquainted with sulphur, expressed oils, and oils distilled *per descensum*. But they knew no other method of extracting the essential oils than by means of the unctuous. We find no account whatever of spirit of wine or ether.

Of the seven perfect metals hitherto known, they were acquainted with all but platinum; but they were ignorant of the imperfect. Some authors, indeed, make a distinction between tin and white lead, which was perhaps zinc, bismuth, or regulus of antimony. But it is impossible to draw any certain conclusion with respect to this; when even Pliny distinguishes between hydrargyrum and argentum vivum.

Expressions, digestions, and decoctions, were almost the only operations in their chemistry. Perhaps indeed they used some varieties of elixation, evaporation, and inspissation; as likewise of crystallisation, sublimation, calcination, distillation *per descensum*, fusion, liquation, vitrification, and fermentation. From the authorities, therefore, already cited, continues Bergman, "it may be naturally inferred, that at the period under consideration the dawn only of chemistry had made its appearance; and that it was rather a collection of unconnected and ill-founded axioms, the result of observation and remarks, than a science established upon the broad basis of an infinite variety of experiments. At this time they were in want also of the proper instruments, and unacquainted with the necessary steps by which the principles of natural bodies can be exactly separated, collected, and properly defined. They were, therefore, without those means so necessary to the evolution of truth, and the construction of a genuine system."—*Physical and chemical Essays*, vol. iii. p. 91.

From the 7th to the 17th century, or what Bergman terms the middle age, many important facts were discovered, and several products were added to the meagre list which has been given. We shall now notice the various new preparations, which include some most important instruments of analysis. It has been mentioned that up to the present period, the acetic acid was the only one known; but several new acids were now added. Basil Valentine described the process for making what he calls oleum vitrioli, a name by which it is commonly yet known, though more correctly called sulphuric acid, from green vitriol, or sulphate of iron; and Dornäus describes another process for preparing the same acid, which, on account of the form of the vessel used in making it, was called oleum sulphuris per campanum. Nitric acid was obtained by Raymond Lully from nitre; his process was much improved by Glauber, who employed, as at the present time, sulphuric acid to decompose the nitre; by this he produced the acidum nitri fumans, or Glauber's spirit of nitre; from common salt the same chemist procured (by means of sulphuric acid the spiritus salis Glauberi, since called marine, muriatic, or hydrochloric acid. Aqua regia was prepared by Hollandus by distilling a mixture of nitre and brine with sulphuric acid; this fluid was so named on account of its power of dissolving gold, the king of metals.

Several salts and some alkaline bodies were also discovered, or became more perfectly known, during this period. Geber describes the process of rendering the alkali of tartar (carbonate of potash) caustic by means of lime; he takes some notice also of the carbonate of soda, and he mentions borax. Glauber described the salt which yet bears his name, the sal mirabile Glauberi, or sulphate of soda; he described also what he terms sal secretus, which is sulphate of ammonia. Raymond Lully added some important observations: he mentions the deliquescent property of potash, and the production of the volatile alkali, or ammonia, by putrefaction; and Basil Valentine notices its evolution from sal ammoniac by the fixed alkalies.

To Crollius chemistry is indebted for the preparation, or at any rate for the description, of several saline substances: thus he terms the salt obtained by saturating vitriolic acid with (the alkali of tartar, tartarus vitriolatus, a name not yet quite extinct; but he does not appear to have been aware that this salt, when obtained by other processes, was similar in its nature. Crollius also mentions the salt or acid of amber; and Bartholetus, sugar of milk. The digestive salt of Sylvius was also discovered by the chemist whose name it bears: it has since been named muriate of potash: its present appellation is chloride of potassium.

Of the earths in general but little was known, and even that little, Bergman remarks, was unsupported by the principles of chemistry; clay was distinguished from sand, but not by its genuine chemical characters. Except alum, few earthy salts were known. Hollandus describes chloride of calcium under the name of sal ammoniac fixus.

Among the metals, antimony was described by Basil Valentine in 1490; bismuth by Agricola in 1530; and zinc by Paracelsus also in the 16th century. Bergman says that Schroeder describes the process of reducing arsenic in his Pharmacopœia of 1649; but Brandt first examined it with considerable accuracy in 1733. Many metallic salts were known and examined in this period. Nitrate of silver was called magisterium argenti, vel chrysalis Dianæ; when fused it was, as now, used as a caustic, and was called by Angelo Sala, lapis infernalis. Crollius gave the appellation of luna cornua to chloride of silver; he mentions also mercurius dulcis, or calomel. The binoxide of mercury prepared by nitric acid, he calls Arcanum Corallinum Paracelsi; acetate of tin, sal Jovis; and oxide of antimony, antimonium diaphoreticum.

Basil Valentine gives an account of acetate of lead, under the name of saccharum Saturni, and mentions the butter of antimony, or chloride; and the white precipitate obtained from it by water is called mercurium vitæ by Paracelsus, and pulvis angelicus by Algarotti. That important medicine, the tartrate of potash and antimony, was first used by Mynsicht, and called tartarum emeticum. Basil Valentine and Paracelsus observed, that chloride of ammonium combined and sublimed with some metallic oxides, producing in the case of iron a compound originally called flores martiales. It has been already noticed, that the sulphates of iron and copper were known by the names of green and blue vitriol, and their nature was understood; in

this period the white vitriol, or sulphate of zinc, was made, though its composition was imperfectly elucidated.

That sulphur was known before the age we are now treating of has been already mentioned; but in this period Basil Valentine describes a solution of it in the fixed alkali, potash. Beguinus mentions it as dissolved in the volatile alkali, or ammonia, and Vigenerus suspected that it was composed of phlogiston and vitriolic acid. Basil Valentine mentions the sulphuric and nitric ethers, but very slightly; but Crollius has described distinctly the art of preparing the former. Thaddeus, Villanovanus, and Raymond Lully describe spirit of wine, and the last calls the strongest spirit alcohol, a name which it yet retains; he mentions the separation of the water by means of carbonate of potash, while Basil Valentine prefers lime for the same purpose. Raymond Lully described the aerated volatile alkali, or carbonate of ammonia. Aëriiform bodies began to excite attention at this period. Van Helmont noticed some of the properties of what he calls gas sylvestre, or carbonic acid gas; he observes that it is invisible, but that it was fixed in bodies, and he attributes the phenomena of the Grotto del Cane to its presence.

From the middle till towards the end of the 17th century several learned societies were formed. The Academy del Cimento was founded at Florence in 1651, the Royal Society at London in 1660, and the Academy of Sciences at Paris in 1666; these societies greatly promoted and advanced physics and experimental chemistry. In 1700 the Prussian Academy also took its rise, on the model of that of France. Before, however, these societies existed, a curious work was published in 1630 by Jean Rey, a physician of Perigord; it is entitled '*Sur la Recherche de la cause par laquelle Estain et le Plomb augmentent de poids quand on les calcine.*' In this work, which excited little or no attention among his contemporaries, the author, without apparently making any experiments, but relying upon those of others, shows that the weight which metals acquire during calcination is derived from the union of air with the metal; he supposes that air is miscible with other bodies besides metals, and states that it may be expelled from water. Rey is generally considered as the person who first showed that air is fixed in bodies during calcination; but in support of this opinion he quotes Libavius, Cardan, and others, as having ascertained the increase of weight in lead by its conversion into a calx.

Newton himself contributed some new and general ideas on chemical phenomena to the Royal Society; he observes that sugar dissolves in water, alkalies unite with acids, metals dissolve in acids, and he inquires whether these effects are not occasioned by an attraction between their particles. Copper dissolved in aquafortis is thrown down by iron. Is not this, he inquires, because the particles of the iron have a stronger attraction for the particles of the acid than those of copper; and do not different bodies attract each other with different degrees of force?

The principal and early chemical investigators of the Royal Society were Boyle, Hooke, and Slare. The first of these was the greatest chemist and one of the most active experimenters of his age; to him the science is indebted for the introduction of tests, or re-agents, for detecting the presence of other bodies; he overturned the idea which was then commonly entertained, that the results of the operation of fire were the real elements of things. Respecting inflammable bodies, acids, alkalies, and combination, he ascertained several important facts. The air pump, which had been invented by Otto von Guericke of Magdeburg, was improved by Boyle and Hooke, and rendered an important instrument in chemical investigations respecting air; they concluded, also, that air was absolutely necessary to respiration and combustion, and that a portion only of the atmosphere was employed in these processes. Hooke, indeed, arrived at the sagacious conclusion, that the part of the air necessary to the above-named processes is the same as that contained in nitre, and that during the chemical process of combustion this matter combines with the burning body.

In 1674, Mayow of Oxford published his tracts on various philosophical subjects. He seems to have been struck with the analogy subsisting between the phenomena of respiration and combustion: many of his conclusions were correct, though some of them were erroneous. He burned a candle under a bell glass, and found the residual air so deteriorated as to be incapable of continuing combustion; he then caused a mouse to breathe a similar quantity of air, and the necessity of its renewal was soon apparent; after this, he put a mouse and a candle together under the same glass vessel, and he found that it lived only half as long as it had existed when alone under the glass. He then reversed the order of experimenting, and endeavoured to fire combustible matter in air which had been spoiled by breathing, and finding no combustion took place, he concluded that "the nitro-aërial particles are absorbed both by the candle and the animal." Mayow's work contains a chapter relating to the "mutual action of salts of a contrary kind," or to chemical combination and decomposition. A great number of new and curious facts are described in this dissertation.

Although a certain degree of similarity is observable in the views of Boyle, Hooke, and Mayow, respecting the operations of combustion and respiration, yet hitherto no theory had been attempted on a broad basis to account for chemical phenomena. But about this period Germany, which still continued the great school of practical chemistry, gained additional credit by the labours of Beccher, who was born at

Spires in 1645; he studied metallurgy and mineralogy with great assiduity; and although he did not greatly add to the collection of chemical experiments, he improved the instruments of research, and rendered manipulation more simple. His opinions were, that the elements of bodies are air, water, and three earths, one of which is inflammable, another mercurial, and another fusible; these three earths, combined with water, he supposed to constitute a universal acid which is the basis of all other acids. He entertained several other notions which are now known to be utterly at variance with the results of experiment; his greatest merit was the contrivance of a theory by which all known facts were connected and deduced from one general principle. This theory was adopted and considerably modified by Stahl, and was by him promulgated in so imposing a form as to be received by the chemical world almost universally for nearly a century. We shall therefore now give a brief account both of this author and his opinions, long known as the Stahlian theory.

George Ernest Stahl was born in the year 1660, at Anspach. The most important of his works is his '*Fundamenta Chymiae Dogmaticæ et Experimentalis*,' which is divided into a theoretical and practical part. The idea that the metals were earthy substances impregnated with an inflammable principle had been advanced by Albertus Magnus. Beccher maintained the existence of this principle, not only as the cause of metallisation, but likewise of combustibility; and Stahl much improved this view of the subject, and supported it by many ingenious and elaborate experiments. To the peculiar principle he gave the name of phlogiston; the doctrine was called the Stahlian theory. It raised the reputation of the author to the highest degree, and placed him in the first rank of chemical philosophers.

In explaining the phlogistic or Stahlian theory, it is to be understood that Beccher and Stahl considered all combustible bodies as compounds; during combustion one of the principles is supposed to be dissipated, while the other remains. Thus when charcoal is burnt, it is entirely dissipated; Stahl therefore supposed that it was phlogiston, or the inflammable principle, nearly pure. By heating charcoal with metals which had been reduced to calces, or what were termed metallic earths, they resumed their metallic appearance and properties; therefore the metals are compounds of metallic earths and phlogiston. Again, by heating Glauber's salt, which is a compound of sulphuric acid and soda, or the fossil alkali, with charcoal, a compound of sulphur and alkali was obtained. Sulphur, therefore, was supposed to be a compound of sulphuric acid and phlogiston. Now, though it had been shown by Boyle that sulphur would not burn without air, and though he had stated that sulphur was contained in the acid, and not the acid in the sulphur, yet Stahl entirely neglected, in forming his theory, the influence of air in producing the phenomena on which it was founded. The first promulgation of the theory overlooked the simple fact which had been before stated, that metals, instead of becoming lighter by being burnt, as ought to have happened had they lost anything, actually become heavier by the operation. Those who afterwards refined upon this theory endowed phlogiston with a principle of levity, and thus the difficulty was for a time removed, but only to be revived with redoubled force; and this difficulty, when it came to be duly appreciated, proved fatal to the theory of phlogiston.

The merits of Stahl are thus briefly stated by Sir H. Davy: "Though misled in his general notions, few men have done more than Stahl, for the progress of chemical science. His processes were, many of them, of the most beautiful and satisfactory kind; he discovered a number of properties of the caustic alkalies and metallic calces, and the nature of sulphurous acid; he reasons upon all the operations of chemistry in which the gaseous bodies are not concerned, with admirable precision. He gave an axiomatic form to the science, banishing from it vague details, circumlocutions, and enigmatic descriptions, in which even Beccher had too much indulged; he laboured in the spirit of the Baconian school, multiplying instances and cautiously making inductions, and appealing in all cases to experiments which, though not of the most refined kind, were more perfect than any which preceded them."

Several chemists of the phlogistic school followed, who contributed to the advancement of chemical science. Caspar Neumann was born at Züllichau, in Germany, in 1682. In 1724 he was appointed professor of chemistry in the Royal College of Physic at Berlin. Dr. Lewis, in the year 1759, published a translation of his works, entitled, '*The Chemical Works of Caspar Neumann, M.D.*,' &c. It would perhaps be difficult to mention any very important discovery contained in this work; but there are several facts which, as facts are always valuable, must still give it a place in the library of a chemist.

John Henry Pott was born at Halberstadt, in the year 1692, and died in 1777. On the death of Neumann, in 1737, he succeeded to the chair of practical chemistry. He was a chemist of great learning and industry. The greater part of his works were collected and translated into French in 1759. In his dissertation on bismuth and zinc, he has collected the statements of all former writers, and described their properties with minute accuracy.

In the year 1709, Andrew Sigismund Margraaf was born at Berlin: he died in 1782. He made some valuable experiments on phosphorus, and on the method of extracting it from urine; he first determined the

properties of alumina, demonstrated the nature of soda, and gave an easy process for preparing pure silver from its chloride. His chemical papers, down to the year 1762, were published at Paris, 1762, in two small volumes; but they do not contain all his memoirs.

In 1630 John Kunckel was born in the duchy of Schleswig; he died in 1702. In 1678 he published a treatise on phosphorus, which had been originally discovered in 1669 by Brandt, an alchemist of Hamburg; all that Kunckel knew of its properties was that it was procured from urine, &c., and from this, after some years' application, he succeeded in obtaining it. The remainder of his works, excepting a treatise on glass-making, are not of great importance.

Nicholas Lemery was born at Rouen in 1645, and died in 1715. He was not the author of any very prominent discovery; but his 'System of Chemistry' contained nearly all that was known respecting the science, and the language in which it was written was more simple than that of those who preceded him. He attempted to explain the cause of earthquakes by an experiment which showed the vivid action that occurs when large quantities of iron filings and sulphur are mixed and allowed to act upon each other.

Homburg was born in 1652, in the island of Java. His papers on chemical subjects were numerous; there are, however, but few of them which are likely to excite much attention in the present state of the science, nor did they greatly contribute to enlarge its boundaries. The pyrophorus known by his name was prepared by mixing human faeces and alum, and heating the mixture to redness till it became a carbonaceous powder. It has been since found that carbonaceous matter in preferable forms may be used with the alum, as honey, flour, or gum. The nature of the combustion of this pyrophorus was first explained by Davy.

Henry Louis Duhamel was born at Paris in 1700, and died in 1781. He published many papers on chemical subjects. His chief contribution to the science was that of pointing out the difference between potash and soda, which had been formerly confounded.

Peter Joseph Macquer was born at Paris in 1718, and died in 1784. He first pointed out the existence of arsenic acid, and the nature of several of the salts which it forms with bases; he afterwards published some important experiments on Prussian blue, and such as tended to the discovery of the nature of its colouring ingredient. He made some experiments on platinum, though without any very beneficial results to chemistry. He was the author of a Chemical Dictionary, which has been translated into many languages.

We have mentioned most of the chemists who contributed valuable additions to the science before the introduction of pneumatic chemistry. To speak of them all would require a volume. We now, therefore, approach, or rather commence, a most important era in the history of chemical research and discovery. Hitherto, except what had been done by Rey, Mayow and Boyle, the effects produced by æriform bodies, and their relation to the phenomena of chemistry, had almost entirely escaped observation; or at any rate they had been but very slightly and imperfectly considered, as shown with respect to the increase of weight which occurs during the calcination of metals, and which was rather attributed to a principle of levity in the phlogiston lost by them, than the acquisition of weight from the air.

Dr. Hales was born 1677, and died in 1761. About 1724 he recommenced the examination of æriform bodies which had previously engaged the above-named philosophers; he attempted to ascertain the chemical relations subsisting between air and other bodies, and to determine the circumstances under which air is absorbed or extricated by natural processes. The results which he obtained were curious and important; but, owing to a fundamental error in his ideas, he drew but few inferences which contributed to elucidate the intricate and hitherto imperfectly explored paths of the science. The idea which he entertained of one elementary principle as constituting elastic matter modified by the effluvia of fluid or solid bodies, greatly aided the formation of those more just views which later and more refined experiments have since contributed to unfold. He subjected a vast number of bodies to the action of heat, and obtained gaseous products from them; thus he found that the air which he obtained from wood was fatal to animals; from nitre he procured nearly 200 times its volume of air, and from coal one-third of its weight. He found that oil of vitrol when poured on the iron filings, produced very little air, but that the addition of water occasioned its evolution in large quantity. In no case, however, were the gaseous products thus procured examined with the attention which might have been expected from the novelty of the results. He also found that when phosphorus was burnt in air, the quantity of air was diminished, and white fumes were produced; but he neither examined the residual air, nor did he inquire into the nature of the white fumes resulting from the combustion of the phosphorus.

The experiments contained in his Statical Essays, published in 1727, were made to prove the transpiration of trees, and also the force with which they imbibe moisture. These experiments are not, however, immediately connected with our present subject.

In 1718 Geoffroy published tables of affinity; and although the affinity has since been discovered to be modified by a variety of circumstances, yet these tables have certainly been of use.

Dr. Black, Professor of Chemistry in Edinburgh, published, in 1756, his researches on calcareous, magnesian, and alkaline substances. He

showed that there existed in these substances an æriform body, possessing chemical and physical properties, perfectly distinct from the air of the atmosphere; he proved that marble and chalk contained this body capable of an æriform existence, and that its presence constituted the difference between them and quicklime; he showed also that it was capable of being expelled from earthy and alkaline substances by the action of an acid, and when the air thus set free was collected and examined, he found it to possess the properties of a weak acid.

Great opposition was offered to the new and important conclusions which were promulgated by Dr. Black: thus, among others, Meyer, a German chemist, attempted to prove that limestone became caustic by combining in the fire with a peculiar substance, and not, as Dr. Black had proved, by losing æriform matter. The loss of weight which the limestone suffered was, however, almost a sufficient proof of the accuracy of Dr. Black's views; and, in a few years from the date of their promulgation, the opinions of Black were universally admitted to be correct.

The existence of an elastic fluid different from that of the atmosphere greatly excited the attention of experimentalists, and they were soon led to inquire whether others might not also exist. The various gases obtained by Hales were now regarded with different views; and, before many more years had elapsed, numerous and peculiar æriform bodies were discovered by various processes. Dr. Black's experiments on what he termed latent heat are remarkable for their simplicity, and the precision of the inferences drawn from them.

Watt derived great advantage from these experiments in his celebrated improvements on the steam-engine.

About the year 1765, Mr. Cavendish (who was born in 1731, and died in 1810,) discovered and described the properties of inflammable air, since called hydrogen gas; and he invented an apparatus for collecting and examining elastic fluids, which, although extremely simple, has been completely set aside by the more convenient methods proposed by Dr. Priestley. He ascertained the relative densities of fixed air, inflammable air, and common air.

Having stated the general properties of hydrogen gas, he shows that different metals, when dissolved in similar portions of the same acid, afford different quantities of this gas: that zinc yielded more than iron, and iron more than tin—facts which are perfectly consistent with and explained by the doctrine of equivalents; he ascertained the exact proportions of the constituent gases of the atmosphere. His most celebrated discoveries were, however, those of the composition of water and nitric acid; and he first determined the freezing point of mercury.

His character, as a philosopher, is thus sketched by Sir H. Davy: "Cavendish was possessed of a minute knowledge of most of the departments of natural philosophy: he carried into his chemical researches a delicacy and precision which have never been exceeded: possessing depth and extent of mathematical knowledge, he reasoned with the caution of a geometer upon the results of his experiments; and it may be said of him, what perhaps can scarcely be said of any other person, that whatever he accomplished was perfect at the moment of its production. His processes were all of a finished nature; executed by the hand of a master, they required no correction; the accuracy and beauty of his early labours, even, have remained unimpaired amidst the progress of discovery, and their merits have been illustrated by discussion, and exalted by time."

The important discoveries of Dr. Joseph Priestley next claim attention. He was born in 1733, and died in 1804. No person ever commenced a career of discovery under circumstances less likely to ensure success than Dr. Priestley. He was but imperfectly acquainted with chemical science, he had but little leisure, his apparatus was very deficient, he had frequently to invent new modes of operating, and with means which were extremely scanty. All these difficulties he surmounted with indefatigable industry and ingenuity, and to him we owe some of the most important discoveries which have ever been made.

Pneumatic chemistry had, to a certain extent, been studied, as already shown, by Boyle, Mayow, Hales, and especially by Black and Cavendish, when Dr. Priestley began his experiments. His first memoir was published in 1772, and was on the method of impregnating water with carbonic acid gas. This paper was the result of his accidentally living near a brewhouse, in which he had made experiments on the carbonic acid evolved during fermentation. Among the gaseous products which Dr. Hales obtained was that now called nitric oxide, but he did not inquire into its properties. It was again discovered and minutely examined by Dr. Priestley, who applied it to the purposes of eudiometry, a branch of the science which may almost be said to have originated with him, and in consequence of this discovery.

Nitrogen gas had undoubtedly been obtained, but was not examined by Hauksbee, when he passed atmospheric air over ignited metals; Dr. Rutherford also noticed it about 1772, and to him the priority of the discovery is generally assigned. It appears, however, that Dr. Priestley had obtained it, and noticed its properties at least as early, and perhaps sooner, for he gives an account of it in the 'Philosophical Transactions' for that year.

His greatest discovery was that of what he called dephlogisticated

air, now called oxygen gas. This important accession to chemical science was made on the 1st of August, 1774. He procured it by strongly heating red oxide of mercury, formed by the action of heat and air upon the metal, and collecting the gas which was evolved from it. The consequences of this discovery would require a volume for description; it has served as the basis for all that is known respecting the nature of the atmosphere, water, acids, and alkalies; and the nature of combustion has been greatly illustrated by it.

Sulphurous acid, fluosilicic acid, hydrochloric acid, and ammonia were first made known in the gaseous state by Dr. Priestley; he discovered nitrous oxide gas, and first obtained carbonic oxide gas, the nature of which however he mistook. He did not discover hydrogen gas, but his experiments upon it are interesting; he pointed out the existence of carburetted hydrogen gas, though he did not make many experiments upon it.

The action of electricity on various compound gases was examined by him, and he showed that an acid is formed when sparks are passed through a confined portion of atmospheric air: this fact served as the basis of Cavendish's discovery of the composition of nitric acid. In the same way, the increase of bulk which he found to take place by the action of the same agent on ammoniacal gas led Berthollet to determine the nature of it. His experiments on the amelioration of atmospheric air by the process of vegetation are highly curious, and have been repeated and confirmed by subsequent investigations. His work entitled 'Experiments and Observations on different kinds of Air' contains a vast number of experiments, from which various inferences might be drawn, which he seems, in his rapid career of discovery, himself to have overlooked: such are those just mentioned; and the composition of atmospheric air and water might be added to the list.

His additions to the means previously known for experimenting on gaseous bodies have afforded the greatest facilities to those who have followed him: such are the invention of the pneumatic trough, and the substitution of mercury for water in the case of those gases which are soluble in the latter fluid. To conclude with the observations of Sir H. Davy: "Chemistry owes to him some of her most important instruments of research, and many of her most useful combinations; and no single person ever discovered so many new and curious substances."

The works of Torbern Bergman (born in 1735, died in 1784) have been collected and translated into English. The first paper which he published was in 1774, 'On the Aërial Acid,' now called carbonic acid gas. If the contents of this paper be compared with the previous one of Cavendish on the same subject, it will be seen that the latter had anticipated Bergman on many of the more important facts. No notice, however, is taken of Cavendish's experiments in it. He afterwards published papers on the 'Analyses of Mineral Waters,' and though the methods which he adopted are by no means accurate, they were preferable to any which had been previously used.

He published a paper on oxalic acid, of which however the discovery is said to be due to Scheele. It will be scarcely possible to enumerate even the various papers of Bergman, and much less to give an analysis of their contents. His 'Essay on Electric Attractions' is however a work of importance, and requires a more detailed notice. The intention of the author was to point out the nature of chemical affinity, and to account for the anomalies which that complicated subject appears to present. He adopts it as a principle that chemical combination is the result of an absolute force. Berthollet attempted to show that this conclusion is erroneous, and though it must be admitted that there are various circumstances which modify the action of this power, we are not so nearly without a guide to just conclusions as the experiments and opinions of Berthollet would lead us to admit.

Bergman published tables in fifty-nine columns, in which he showed the relative attraction of bodies, or what he terms elective affinity. As the order of decomposition often varies, according as it is made in the dry way or the moist, each of the fifty-nine columns was divided into two; the first exhibiting the order of decompositions in the moist, and the second in the dry way. He also stated various cases of double decomposition. These tables are constructed upon the now well-known principle, that any substance, whether acid, alkali, or metallic oxide, being placed at the head of a column, and others under it, such substance has the greatest affinity for that next to it, and for the rest, according to the nearness of their place.

It has been already observed, that Bergman's processes for analysing mineral waters were more correct than any which had been previously adopted, and although his experiments on the analysis of precious stones are far removed from perfection, yet they possess the rudiments of the methods which are now adopted. He first proposed the analysing of minerals by combining them with the fixed alkalies, by which they were rendered partially soluble in water, and totally so either in that fluid or in an acid.

He found fulminating gold to yield ammonia; and he explains the detonation to arise from the sudden decomposition of that gaseous body.

The discoveries which next claim attention are those of Charles William Scheele, who was born at Stralsund in 1742, and died in 1786. Like Priestley, Scheele began his experiments under very unfavourable circumstances with respect to apparatus and the means of procuring it.

Scheele, observing that air was requisite to combustion, subjected it to analysis. He found that certain substances, especially what was then termed liver of sulphur, and now sulphuret of potassium, when exposed to a given bulk of air, diminished it to about four-fifths of the original quantity; he found also that the flame of burning sulphur and of hydrogen gas produced the same effect. Without any acquaintance with what Priestley had previously done, he obtained, by various processes, oxygen gas, which he termed empyreal air; and he showed that this air was absorbed by liver of sulphur; and that upon adding fresh empyreal air to that left unacted upon by it atmospheric air was reproduced.

His experiments on the nature of air were followed by some on heat and light, and he gave the name of radiant heat to that portion of it which emanates from hot bodies, and, as he found, in right lines. He observed the blackening effect which is produced by the sun's rays on chloride of silver, and that the violet rays produce this effect most speedily. He made experiments on Homberg's pyrophorus, and showed that ammonia alum is incapable of forming it. In his dissertation on manganese, he made the discovery of chlorine gas, or, as he called it, dephlogisticated marine acid. His essays on fluor spar contained several valuable facts, but he committed the error of supposing that the silica which he obtained in his operations, from the retort, was formed by the combination of water and fluoric acid. He pointed out the difference between plumbago and sulphuret of molybdenum; and he first described the molybdic and arsenious acids, and formed a compound of the latter with oxide of copper, arsenite of copper, which has since been extensively used as a pigment, under the name of Scheele's or mineral green. He made experiments on milk, and sugar of milk; and the acid of the sugar of milk, now called lactic acid, was noticed by him. He gave a method of obtaining citric, tartaric, gallic, and some other vegetable acids; and published essays on tungsten, ether, calomel, benzoic acid, and urinary calculi, all of which contain valuable information.

He particularly examined the colouring matter of Prussian blue, which was nearly his last contribution to chemical science. The subject was one of great difficulty, considering that it involves the agency of nitrogen, which had not long been discovered. He treats the subject, however, with his usual sagacity; and having obtained what is now called prussic or hydrocyanic acid, he stated several of its properties. Besides the discoveries which have been enumerated, it is to Scheele that we are indebted for the first knowledge of baryta and of the character of manganese.

Antoine Laurent Lavoisier was born in Paris in 1743, and died a victim to the revolution in 1794. Although the original discoveries of Lavoisier have less merit than those of Priestley and Scheele, yet his contributions to the science are numerous and important, especially as to what regards its theory. His 'Elémens de Chimie' were published in 1789. In this work he considers heat as a subtle fluid or a material substance, which he calls caloric. He argues that the different forms of matter depend in general upon the quantity of caloric which they contain. His analysis of atmospheric air, though conducted perhaps on more philosophical principles, does not offer so great precision of results as those deducible from the very simple experiment of Priestley; but it must be admitted that they had the merit of settling the question as to the nature of the atmosphere.

Van Helmont, and after him Macquer, had employed the term gas to denote all elastic fluids which differ from atmospheric air. This word Lavoisier also adopted; and as he found that the portion of the atmosphere which supported animal life also entered into the composition of acids, he called it oxygen gas; the other constituent of the air he called, from its fatal effects upon animal life, azotic gas, now called nitrogen, a name derived from its producing nitric acid.

Lavoisier and his coadjutors effected various improvements in chemical nomenclature, most of which remain in use at present. The nature of the diamond had excited the attention of the Florentine Academy as early as 1690; the subject was resumed by Lavoisier, who proved, that when air was excluded it underwent no change; on the other hand, he showed, that by burning it in oxygen gas carbonic acid was formed, and hence he argued, what has since been more strictly demonstrated, that the diamond, in its chemical nature, is similar to common charcoal.

In adverting to the solution of metals in acids, he notices the necessity of their oxidisement previously to it; and hence he argues the probability that the alkaline earths are metallic oxides, the oxygen serving as a bond of union between them and the acids: this sagacious remark was verified by the discoveries of Davy. In his additional observations on the combinations of oxygen, he mentions the conditions necessary for its union with different bodies; the compounds arising from the union of various combustible bodies are also treated of, and those of the acids and some other compound substances. Sir H. Davy remarks, that "Lavoisier must be regarded as one of the most sagacious of the chemical philosophers of the last century; indeed, except Cavendish, there is no other inquirer who can be compared to him for precision of logic, extent of view, and sagacity of induction. His discoveries were few, but he reasoned with extraordinary correctness upon the labours of others. He introduced weight and measure, and strict accuracy of manipulation into all chemical processes. His mind was unbiassed by prejudices; his combinations were of the most

philosophical nature; and in his investigations upon ponderable substances he has entered the true path of experiment with cautious steps, following just analogies, and measuring hypotheses by their simple relation to facts."

It is, however, matter of history, and ought not to be suppressed, that Lavoisier was not content merely to employ the discoveries of others, even without acknowledgment, but that he made a distinct claim to the discovery of oxygen, a claim which Dr. Priestley satisfactorily refuted, by asserting, what might have been contradicted, but which was not, that he had mentioned this gas and the mode of procuring it at the table of M. Lavoisier himself. He makes scarcely any, if any, acknowledgment of the labours of his predecessors, and his friends have claimed for him the discovery of nitrogen gas, previously described by Priestley and Rutherford.

Claude Louis Berthollet (born in 1748, died in 1822) was the author of more than eighty memoirs on chemical subjects. His earlier papers on sulphurous acid, ammonia, and the decomposition of nitre, were published while he was yet a believer in the phlogistic theory, which he zealously defended, but afterwards renounced. One of his most important contributions to chemistry was that of demonstrating, in 1785, the nature and properties of the elements of ammonia. About the same time he made his experiments on the dephlogisticated marine acid of Scheele, which, from experiments well calculated to give rise to the opinion, he supposed to be a compound of muriatic acid and oxygen, and it was called oxygenised muriatic acid. These views, in consequence chiefly of the experiments of Davy, have been shown to be erroneous; and this gas is now called chlorine, and is admitted to have hitherto resisted all attempts at decomposition. It was stated by Scheele, in his experiments on this gaseous body, that, among other properties which it possessed, was that of destroying vegetable colouring matter. In consequence of this remark, Berthollet applied it to the purpose of bleaching, in which it is now most extensively and almost universally used.

The experiments which Berthollet made on prussic acid and its compounds advanced, but did not complete, our knowledge respecting those bodies. In examining the properties of sulphuretted hydrogen, he observed that it possessed acid properties; it was not however by the French chemists admitted to the class of acids, because it was inconsistent with the theory just adopted, that all acids must contain oxygen. Berthollet also discovered fulminating silver, and first employed alcohol as a solvent for obtaining potash and soda in a pure state.

In 1803 Berthollet published a work entitled 'Chemical Statics,' the object of which was to controvert the opinions of Bergman on chemical affinity; but although he pointed out some difficulties attendant upon them, they were by no means refuted. In this work Berthollet also maintained the opinion that quantity may be made to overcome the force of the chemical affinity existing between bodies. There were, however, several points of the argument which he neglected, or with which he was unacquainted; indeed, at the period at which he wrote, the doctrine of definite proportions had not been promulgated,—a doctrine which will explain many of the apparent anomalies that occurred to Berthollet. Indeed, in a discussion with Proust in which the latter had decidedly the advantage, Berthollet asserted that bodies were capable of uniting with each other in all proportions. But whatever may have been the erroneous views of Berthollet in some particular cases, chemistry is greatly indebted to him for many valuable discoveries and minor details; and the application of the bleaching power of chlorine is a practical scientific improvement which has, for its extent and usefulness, scarcely been surpassed.

Louis Bernard Guyton de Morveau was born at Dijon in 1737, and died in 1816. Although the publications of this chemist were very numerous, and contributed much to the extension of the science, yet he was not the author of any very prominent discovery. His papers are scattered through the 'Dijon Mémoires,' 'Journal de Physique,' and 'Annales de Chimie.' There are, however, some circumstances connected with the history of chemistry in which his participation must not be overlooked. In 1787, in conjunction with Lavoisier, Berthollet, and Fourcroy, he published a work in one volume 8vo, entitled 'Méthode de Nomenclature Chimique,' in which the important improvements projected and subsequently adopted are detailed. In 1801 he published a tract, 'Des Moyens de désinfecter l'Air.' For this purpose he used various acids, and especially hydrochloric acid; but he afterwards adopted chlorine, which is now so generally used for the same purpose. The application of these disinfectants was made in 1782, although the history of it was not given to the public till the year above mentioned. He was the author of a considerable portion of the chemical articles in the 'Encyclopédie Méthodique;' and that on 'Acid' has been justly commended for its accuracy, both as to experimental and historical details. [GUYTON DE MORVEAU, in *BIOG. DIV.*]

Antoine François de Fourcroy was born at Paris in 1755, and died in 1809. This chemist was more celebrated as one of the first authors, if not the earliest, of a treatise on chemistry, and as a lecturer, than as a promulgator of any very great discovery. His chemical work went through several editions, and is in general written with perspicuity and attention to the history of the science. His 'Philosophy of

Chemistry' is also a work of considerable merit. As a discoverer, he is to be mentioned as having first shown that the salts of ammonia and magnesia have a tendency to form double salts; and he particularly pointed out the ammoniaco-magnesian phosphate. He ascertained that biliary calculi resemble spermaceti in their nature; and he imagined that muscular flesh is convertible into a fatty substance, which he named adipocire. He published several papers in conjunction with Vauquelin, but what belongs to each it is impossible to tell. It has been supposed that the facts were principally ascertained by Vauquelin, and the account of them written by Fourcroy. Among other papers, they published one giving a method of obtaining baryta from the nitrate by heat; they discovered also the existence of phosphate of magnesia in bones, and of phosphorus in the brain and in the melts of fishes.

It has been mentioned, that the analysis of precious stones had, though imperfectly, been attempted by Bergman: this department of chemistry received vast accessions from the labours of Martin Henry Klaproth, who was born at Wernigerode in 1743, and died in 1817. This chemist introduced into the art of analysis more improvements than we can even allow room to detail. The vast progress which he made in the science will be fully estimated when it is known, that at the time at which he commenced his labours the correct analysis of scarcely any minerals was known, and that he analysed nearly two hundred with so much accuracy that his results have been generally confirmed, whilst the simplicity of his method of operation is greatly to be commended. In 1789 he discovered a new metal in a mineral called pechblende, to which he gave the name of uranium; and in the same year, in analysing the zircon, he found a new earth, which he called zirconia, and which has since been shown by Berzelius to be a metallic oxide. In 1795 he found the same substance in the hyacinth; in this year he also found in the red schorl the same metallic oxide which Gregor had previously met with and called menachine. Klaproth named it titanium, and this appellation is now generally employed. Apparently ignorant of the fact that strontia had been previously described as a peculiar earth, he in 1793 showed the difference between it and baryta, they having been confounded in Germany up to that time. In 1798 he gave an account of tellurium as a new metal, but it had been before noticed by Müller. In 1804 he described a new substance, which he called ochroita. Berzelius and Hisinger considered it a metallic oxide, and called the metal cerium. Besides these more important contributions to science, he made many discoveries of minor importance, which may be found in his 'Analyses,' of which two volumes were published and translated into English. Besides minerals, there will be found analyses of some mineral waters, an account of the effects produced by intense heat upon various minerals, and the details of the methods of analysis, which are extremely valuable and instructive, both as to the nature and method of employing various chemical reagents.

M. Vauquelin was one of the most distinguished analysts of the present century. He was born in Normandy, in what year we know not; but he died in 1829. His analyses were not confined to any particular class of bodies, and he published more and perhaps included a greater variety in his operations than any other chemist; his researches included the three kingdoms of nature, but his greatest discoveries were in the mineral. In the emerald and beryl he found a new earth, to which, on account of the sweetness of the salts which it formed with acids, he gave the name of glucina; but his discovery of chromium, in the state of chromic acid, in the red lead of Siberia, was an era in chemical history. Originally met with in a scarce and valuable mineral, it has since been found in various parts of the earth combined with iron, and in immense quantity; it is largely employed for various uses; in the state of oxide for giving a green to porcelain; in that of acid, combined with oxide of lead, it forms both a fine yellow and orange chromate, which is used in painting and calico printing. It would be in vain to attempt an analysis of Vauquelin's various papers; they are chiefly to be found in the 'Annales de Chimie,' and will amply repay perusal. He was also author of a work entitled, 'Manuel de l'Essayeur,' which he was particularly competent to write, not merely on account of his great skill, but also as being assay-master of the mint. [VAUQUELIN, in *BIOG. DIV.*]

Mr. Smithson Tennant was born in Yorkshire in 1761, and died in 1814. In 1791 he made an experiment, which confirmed the previous statement of Lavoisier as to the composition of carbonic acid. He effected this by passing phosphorus through red-hot carbonate of lime, and he found that the phosphorus was acidified at the expense of the oxygen of the carbonic acid, and that while phosphoric acid was formed charcoal was developed. In 1796 he heated the diamond with nitrate of potash in a gold tube, and he found that the diamond, by combining with the oxygen of the nitric acid, was converted into carbonic acid, and this combined with the potash of the decomposed nitrate to form carbonate of potash. He observed in 1799 that certain limestones, on account of the carbonate of magnesia which they contain, are hurtful to vegetation; he examined the substance known by the name of emery in 1802, and showed that it is a variety of corundum; and in 1804 he discovered two new metals, viz., osmium and iridium, in the grains of native platinum.

John Gottlieb Gahn (born in 1745, in South Helsingland, died in 1818) was the pupil of Bergman. He was particularly skilled in the

use of the blowpipe; and he ascertained that bone is a compound of phosphoric acid and lime. He proved the metallic nature of manganese, and stated the properties of the metal.

The Rev. William Gregor was born in 1762, and died in 1817. In the year 1791 he discovered a peculiar substance in a black sand, found in the parish of Menaccan in Cornwall. This substance was afterwards detected by Klaproth, and by him proved to be a metallic oxide, to the metal contained in which he gave the name of titanium. In 1805 Mr. Gregor described a hydrate of alumina found in Cornwall; he analysed the uranite, and also the arseniate of lead.

Dr. William Hyde Wollaston was born in 1776, and died in 1828. [WOLLASTON, in BIOG. DIV.] His knowledge was not confined to chemistry: he made acoustics and more particularly optics also his study. His first chemical paper on urinary calculi contained much new information on this subject: he showed that the mulberry calculus is oxalate of lime mixed with animal matter; he pointed out a new calculus, which he named cystic oxide, the nature of the triple phosphate, and of the chalk stones formed on the joints of gouty persons. He discovered two new metals in the grains of native platinum, namely, palladium and rhodium; he showed that oxalic acid and potash combine in three different proportions, forming the oxalate, binoxalate, and quadroxalate of that alkali. He pointed out the nature of some small copper-coloured crystals found in the slag of an iron furnace, proving by a series of experiments, in a paper which is a perfect model of conciseness and accuracy, that they were metallic titanium. He perfected the method of rendering platinum available for the purposes of chemistry and the chemical arts, and his 'Scale of Chemical Equivalents,' more effectually elucidated and extended the doctrine of definite proportions than all that had been previously done both by theory and practice. He first showed that the evolution of voltaic electricity is dependent upon chemical action, a fact which has been since amply and ably illustrated by Faraday. His 'Reflective Goniometer' has given to crystallography all the minute accuracy which it previously stood in need of; for it showed that three substances, namely, the carbonate of iron, lime, and magnesia, which were previously supposed to crystallise in rhomboids measuring the same angles, had all different angles. His paper on the finite extent of the atmosphere is replete with curious and acute observations; and he invented some optical instruments, which we need not here particularly describe.

Humphry Davy was born at Penzance, in Cornwall, in 1778, and died in 1829. [DAVY, in BIOG. DIV.] To the researches and discoveries of this justly celebrated chemist it will be impossible to do justice in the space to which we are confined. His first contributions to chemical science were published in 1799, in a work edited by Dr. Beddoes, entitled 'Contributions to Physical and Medical Knowledge.' The first paper is 'An Essay on Heat, Light, and the Combinations of Light,' and the second 'On the Generation of Phos-oxygen (oxygen gas), and on the Causes of the Colours of Organic Beings;' these, although stamped with the mark of genius, are more remarkable for the speculative than experimental nature of their contents. In 1800 he published a work, entitled 'Researches, Chemical and Philosophical; chiefly concerning Nitrous Oxide, or Dephlogisticated Nitrous Air, and its Respiration.' In this, which is a work of high merit, he details the effects produced by the respiration of nitrous oxide both on himself and others. The very high reputation which he had acquired by this work was greatly increased by his paper in the 'Philosophical Transactions' for 1807, entitled, 'On some Chemical Agencies of Electricity.' In this paper he showed that the acid and alkali which had before been observed to be developed by galvanic agency were derived from the decomposition of some previously existing salt, and were not formed by the electric action. He arrived at the conclusion, from the numerous experiments described in this paper, that all bodies possessing chemical affinity for each other are in different electrical states, and that the degree of the affinity is proportional to their intensity. By the agency of voltaic electricity he decomposed the alkalies, potash and soda, and obtained from them metallic bodies, to which he gave the names potassium and sodium; he succeeded also in separating metals from lime, baryta, strontia, and lithia; he was not however equally successful in decomposing those earths which have no alkaline properties, as alumina, glucina, yttria, and zirconia, though these have since yielded to other modes of decomposition. In 1807 he also discovered boron, the metalloid of boracic acid.

In 1811 Davy read a paper to the Royal Society, in which he showed that what was called oxymuriatic acid by Berthollet, instead of being, as he supposed, a compound of oxygen and muriatic acid, was, in fact, an undecomposed substance, and therefore must be regarded as an element, and he gave to it the name of chlorine from its green colour. These views, though at first strongly opposed by Berthollet and Dr. Murray, are now universally adopted. In the following years he contributed various important papers to the Royal Society, and among them the following:—On a compound of chlorine and oxygen; on chloride of nitrogen; on iodine; the combustion of the diamond; on the salts called hyperoxymuriatic; on fire-damp, and the means of preventing accidents in mines; and his invention of the safety lamp; a similar, but less successful, form of safety lamp, depending however upon entirely different principles, having been just previously invented by Stephenson. In succeeding years he published various papers on electricity, electro-magnetism, and on a method of preventing

the corrosion of copper sheathing; this plan, though based on sound philosophy, failed in its object, from the very unexpected cause of the sheathing being rendered foul. His last paper was in 1819, on the electricity of the torpedo.

In 1812 Davy published the first part of the 'Elements of Chemical Philosophy,' a work which was never completed. It embodied the results of his discoveries, and an account of certain views of the author up to the time at which it appeared. This work bears occasional marks of haste, yet it contains evidence of its emanating from a genius of the highest order.

In concluding this brief sketch, it is hardly necessary to remark that the discoveries alluded to in it placed their author at the head of the science which he illustrated, not merely in England but in Europe; and his fame will rest on the durable base of experimental discovery and great talent for generalisation.

In giving a history of chemistry, it is impossible not to notice the doctrine of definite proportions, or the atomic theory; under which head we have entered pretty fully into the history of its discovery, and mentioned the contributors to its development, whether deceased or living. In that article the discoveries and labours of Wenzel, Dr. Higgins, Mr. Higgins, Richter, Proust, Dalton, Wollaston, Berzelius, Gay-Lussac, and Prout, are detailed so amply as to require no further notice here.

There are still some other subjects which it is necessary to mention, though we cannot allude to all the discoveries which their respective authors have made. In 1803, Sertuerner, a German apothecary, discovered in opium the first of a new class of alkaline bodies, or the vegetable alkaloids, but this discovery excited little notice, till the author published a second paper in 1816; this alkaloid is morphine. Since this time numerous others have been found; they are most of them very active substances, and frequently poisonous. Thus the different kinds of cinchona have yielded amongst others two alkaloids, quinine and cinchonine, to which their virtues are owing: these were discovered by Pelletier and Caventou, in 1820. It has been found that many of the most active vegetable substances, such as hemlock, nux vomica, tobacco, and many others, contain alkaloids.

In 1812, iodine, a peculiar elementary substance, was discovered by M. Courtais, of Paris. The nature of this body was made the subject of numerous experiments both by Davy and Gay-Lussac. Its discovery served the purpose of illustrating and confirming the new views of Davy as to the simple nature of chlorine.

In 1818 Berzelius discovered a peculiar inflammable elementary body, to which he gave the name of selenium. In 1824 he obtained the elementary bases of silica and zirconia; and in 1829 he found a new metal, to which he gave the name of thorium. In 1818 Stromeyer discovered cadmium, a new metal; and in the same year lithium was discovered by Arfwedson; Bussy obtained magnesium from its oxide in 1829, and in 1830 Sefstrom discovered the metal vanadium.

Up to this time the study of organic chemistry had been little cultivated, the difficulties surrounding the analysis and investigation of organic compounds having greatly contributed to retard the progress of knowledge in this direction. These difficulties were to a great extent removed by the early labours of Liebig, who, in conjunction with Berzelius, drew universal attention to this branch of the science, rendering it, even to the present day, the most attractive field of research to the chemical investigator. To these chemists is due the origination and development of the radical theory of organic compounds, a theory, the value of which, in stimulating and directing investigation, and in facilitating the study of organic compounds, can scarcely be overrated. It served as a thread in the daily widening labyrinth of organic bodies, guiding the investigator to new discoveries and generalisations. Still more recently this branch of the science has received a not less important impulse from the labours of Laurent and Gerhardt; the originality of thought and unwearied industry of these chemists render their early death a grievous loss to science.

We cannot better conclude this slight sketch of the progress of chemistry than by adopting the words of Sir H. Davy on a similar occasion:—"To dwell more minutely upon the particular merits of the chemical philosophers of the present age will be a grateful labour for some future historian of chemistry; but for a contemporary writer it would be indelicate to assume the right of arbitrator, even where praise only can be bestowed."

CHEMISTRY, as applied to Agriculture. [RURAL ECONOMY.]

CHENOCHOLIC ACID. The soda salt of this acid is said to be contained in the bile of the goose, but as its composition is not known, its existence as a separate acid is doubtful.

CHEQUE, a written order on a banker by a person who has money in the bank, directing him to pay a certain sum of money to the bearer, or to A. B. or bearer, or to A. B. or order, which is signed by the drawer. In order to exempt this instrument, so nearly resembling a bill of exchange, from the stamp duty imposed in respect of bills, it was required by the Stamp Act of Geo. III. (55 Geo. III. c. 184), still in force, (1) that it be for the payment of money to the bearer on demand, (2) and be drawn upon a banker residing or carrying on business within fifteen miles of the place of issue, (3) that the actual place of issue be stated in the cheque, (4) that it bear date on or before the day of issue, (5) and that it do not direct payment to be made in bills or promissory notes. The Act, 21 Vict. c. 16

imposed a stamp duty of one penny, to be denoted by an adhesive or impressed stamp cancelled with the signature or initials of the drawer, and permitted the instrument to be also drawn payable to order. A later Act permitted it to be negotiated or transferred beyond the distance of fifteen miles from the bank on which it is drawn, subject to a stamp duty of one penny; and the 21 Vict. c. 20, leaving existing enactments unrepealed, imposes a stamp duty of one penny on all cheques indiscriminately.

A cheque may be drawn for any amount not less than twenty shillings, but under that sum it is void; and any person issuing a cheque drawn for a less sum, or on which a less sum remains payable, incurs a penalty. The utmost care, however, should be observed in writing in the amount, to avoid any carelessness which would facilitate fraudulent alterations, otherwise the result of a successful fraud will fall upon the drawer and not upon the banker. Cheques have for a long time formed a considerable part of the circulating medium of the country, being transferable, if payable to bearer, by delivery, or, if to order, by indorsement, and, as they are payable on demand, there is no time when they may be said to be overdue. But it is a rule of law that a cheque should be presented for payment by the holder or his banker when in the same place with the banker on whom it is drawn, within banking hours on the day after the holder received it, or should be despatched by the post of that day, or the then earliest post from the place, when the banker by whom it is payable carries on business at a distance; otherwise all previous holders are discharged from their liability by the undue delay, and even the drawer is not liable if he has suffered loss in consequence thereof through the failure of his banker in the meantime.

The person to whom the amount of a cheque may be validly paid must be the legal holder, the person, namely, who is capable of giving a discharge for the money, otherwise the banker pays it in his own wrong; but where the cheque is drawn payable to order, the banker is exempted by statute from proving that the first indorsement is genuine, if it purport to be the indorsement of the payee. If the drawer, however, or any subsequent holder, cross the cheque with the name of a banker, or with the blank formula, "— and Co.," the person receiving the money must be a banker, and none but the particular banker, if any is named, in the crossing upon the cheque. Such crossing is, by the 19 & 20 Vict. c. 25, made part of the cheque and may not be obliterated, altered, or added to by any person, except to insert the name of a banker in the blank formula, without rendering the cheque itself thereby void, and the person who fraudulently so alters it liable to be indicted for forgery.

The banker on whom it is drawn is bound to pay the cheque of his customer immediately on presentment, if he has sufficient funds of the drawer, and a refusal, in that case, to do so subjects the banker to an action for damages at the option of the customer, without proof of pecuniary loss accruing to him therefrom. If the banker pays a cheque with a forged signature to it, or if he pays a sum of money exceeding the amount originally written in the cheque, he does so in his own wrong, and is liable to repay either the whole amount or such sum as he has paid in excess of the original amount so fraudulently altered. But in the case of a crossed cheque, if, at the time when it is presented for payment, it does not plainly appear to be or to have been crossed, or such crossing to have been obliterated, added to, or altered, the banker incurs no liability by paying it, or by paying it otherwise than to a banker, or to the banker named in the crossing respectively, unless in so doing he act *malâ fide* or with negligence.

(*Chitty on Bills of Exchange*, 10th ed., by J. A. Russell, LL.B., and David MacLachlan, M.A.)

CHERRY, a valuable fruit, of which great numbers of varieties are known in our gardens; they are all the produce of *Cerasus avium*, or *C. vulgaris* [CERASUS, NAT. HIST. DIV.], or of plants obtained by the intermixture of those two original species. Independently of their value as an article of luxury, and as yielding by distillation such liqueurs as Maraschino (so called because the Dalmatian *Maraschi* cherry is employed in its manufacture) and Kirschenwasser, cherries contribute essentially to the support of the poorer classes in some countries, not only in puddings and tarts, but as a principal ingredient in a kind of soup, and as a dried provision for winter. Their timber moreover is valuable for the more common kinds of cabinet-maker's work, and as in favourable soils they grow fast, they often afford to the planter a quick and good return for the outlay of his money. It is however only upon light sharp well-drained soil that the cherry thrives; when planted in stiff and wet soils it grows slowly, gums very much, and falls into a state of incurable bad health. Its varieties are multiplied by budding or grafting, operations best performed upon the common wild cherry, the stones of which are collected by the nurserymen for that purpose. Like all other fruit trees that have been objects of cultivation, the cherry has given rise to a multitude of varieties, from among which it is difficult for any but professed gardeners to know how to make a selection. We should say that for all useful purposes the following are sufficient. The earliest are the Black Tartarian, and the Early Purple Guigne; the Early May, which ripens close about the same time, is not worth cultivation; these are succeeded by the May Duke, the Bigarreau, the Elton, and the Black Eagle; the Late Duke is the latest of the sweet cherries. For puddings there is the Kentish; for preserving in brandy, the Morello;

for drying, the Belle de Choisy, the Flemish, and the Kentish. These are amply sufficient for a small garden, and are all good bearers: the Morello only actually requires a wall. If more variety is wished for, the Black Heart and the Downton may be added: and these are all out of the two hundred and nineteen varieties mentioned in the Horticultural Society's valuable Fruit Catalogue which are at all worth cultivating.

CHERUSCI, a celebrated people of ancient Germany, reckoned by Caesar as of equal importance with the Suevi, who bordered on the Catti and the Chauci, living inland or south of the latter, and near the banks of the Visurgis or Weser. The Cherusci, with their confederated tribes, excited by Arminius, joined the Catti and others in the attack and defeat of Varus and his legions. They were afterwards defeated by Germanicus in the Teutoburg forest, but not subdued. After Germanicus left Germany and the Romans had drawn their legions back to the banks of the Rhine, the Cherusci quarrelled with the Suevi, and afterwards with the Catti, by whom they were conquered and lost much of their original consequence. Under Claudius the Cherusci sent messengers to Rome, to ask, as a king, for one Italicus, of the race of Arminius, who was born at Rome, of German parents. Italicus, however, on his arrival in Germany, was looked upon by many of his countrymen as an alien, and a degenerate descendant of Arminius. He was expelled from his kingdom, but afterwards recovered it with the assistance of the Langobardi. (Tacitus, 'Annot.' xi. 16, 17.) In the time of Tacitus the Cherusci had declined from their former importance, having been overpowered by the Catti and other neighbouring tribes, and were considered as having degenerated. ('German.' 36.) Their last appearance is at the beginning of the 4th century, when they formed a part of the confederation of the Franks.

CHERVIL, a culinary vegetable, the *Scandix cerefolium* of botanists; it is an annual, and a native of the south of Europe; its leaves have a slight aromatic taste, and are used in soups and salads: it is little cultivated.

CHESS is an intellectual game, played on a chequered board of sixty-four squares by two persons, each furnished with sixteen men, eight of which are called *pieces*, and the other eight *pawns*, and moving alternately. One set of men is usually white and the other black. They are as follows:—

WHITE.		BLACK.
	King.	
	Queen.	
	Rook or Castle.	
	Bishop.	
	Knight.	
	Pawn.	

Chess is not only distinguished from other games by the large amount of intellect which may be brought to bear upon it, but also by its literature, which would fill a tolerably large library, and this literature is constantly increasing among all nations that practise the game. It consists in the *first* place, of learned inquiries into the origin of the game; *secondly*, of treatises on the game, its laws and institutes, instructions for openings and endings of games, and analyses of the various recognised openings; *thirdly*, of collections of games by distinguished players, usually accompanied by notes pointing out beauties or defects in the play; *fourthly*, of problems or end-games, in which the student is required to give mate in a certain number of moves, or to comply with certain other conditions. A large number of monthly and weekly journals, both in Europe and America, are either wholly or in part devoted to the recording of games and problems and general chess intelligence, together with essays on points which are constantly arising, or which still remain unsettled. *Lastly*, there is much miscellaneous literature, consisting of biographical notices of distinguished players, anecdotes, sketches, tales, and poems. The Latin poem on chess by Vida, bishop of Alba, published at Rome in 1527, under the title of 'Scacchia Ludus,' is well known. The earliest writer in Europe was Cesolis, a Dominican friar, who wrote probably before the year 1200. A Latin edition of his treatise was published in 1473, and a French edition in 1460, from which an English version was made by Caxton, and printed by him at Westminster in 1474, and it enjoys the high distinction of being the first book printed in England with moveable types. Early books on chess are in great request among book-collectors, and they fetch high prices.

History.—It is not in our power, within the limits of this article, to give more than the most meagre sketch of the history of chess. Various nations claim the honour of its invention, and their respective claims are brought together within a readable compass in Mr. Tomlinson's 'Amusements in Chess.' We pass over them the more willingly since Dr. Duncan Forbes, professor of Oriental languages in King's College, London, in a series of papers originally published in

the 'Illustrated London News,' and collected in a pamphlet for private circulation, has settled the matter in favour of India, adopting the conclusion of Dr. Hyde and Sir William Jones, that "Chess was invented in India, and thence introduced into Persia and other Asiatic regions during the 6th century of our era." The origin of the game is altogether lost, but it seems to have existed for several thousand years before the 6th century of our era. The ancient Hindu game is called "Chaturanga," a term compounded of the two Sanscrit words *chatur* "four," and *anga* a "member" or "component part." The term "shatranj," used by the Persians, Arabs, and Turks, is a corruption of the word *chaturanga*. The board consisted then, as it does now, of sixty-four squares, but the game was played by four persons, each having a king, a rook, a knight, and a bishop (the last being represented by a ship), together with four pawns. The two opposite players were allied against the other two, and the moves were decided by the turn of an oblong die, having four faces, marked with the numbers 2, 3, 4, and 5. The pieces were arranged for play as in the following diagram, in which the green and the black are allied against the red

Diagram 1.

and the yellow. The rook represents the elephant, and the bishop in the corner the ship. The king, rook, knight, and pawns, had the same moves and powers as at present, only the pawn could move but one square at starting. The bishop moved diagonally to any third square, passing over the square next him, which he did not command or attack, and his move was not restrained by any piece in the intermediate square. Another peculiarity was, that not one of the four bishops could attack any of the squares on which the three others were allowed to move. The throwing of the die determined which piece was to be moved. Should the number five turn up, the king or one of the pawns must move; if four, the elephant; if three, the horse or knight; and if two, the ship. The object of each player (the green, for example, or, as we should call him in modern chess, the white) was in the first place to convey the two centre pawns to the opposite end of the board, in order that they might be promoted to the rank of knight or rook, which would nearly double the strength of the player. Another great object was to convey the king, by a series of careful moves, to the square of his ally, the black king. This would give white the command of the allied forces, with a great increase of power. In the mean time, white took every safe opportunity of damaging or exterminating the hostile forces, and having gained his ally's throne and the command of his forces, the main point then was to capture the hostile kings, and gain the "chaturaji," which was equivalent to our checkmate. For minor points and matters of detail, we must refer to Dr. Forbes's papers; but we may say a few words respecting the mode by which the ancient *chaturanga* probably became gradually changed into the *shatranj* or mediæval game. In the former, it was a great point with each of the four players to gain possession of his ally's throne, since by that means he had the undivided command of the allied forces. Hence it must often have happened that, after some twenty or thirty moves, the contest remained to be concluded between two players only, a circumstance which was in itself sufficient to have given rise to the mediæval game. There is also evidence that the *chaturanga* was frequently played by one person only on each side; and as the law and religion of the ancient Hindus strictly prohibited gaming, the use of the die must have been discontinued at a very early age, whereby the game became one of skill and strategy alone. In arranging the allied forces on one side of the board, certain alterations were made. The elephant or rook, and the ship or bishop, were made to change places, whereby the bishop gained more freedom of action. But the most important change was to reduce one of the allied kings to a subordinate situation, called in the Sanscrit "*mantri*," and in the Persian "*farzin*," both of which mean monitor or councillor. Thus, by a slight alteration in form, and none in principle, we have the men arranged as in modern chess. This is the game of *shatranj*, which was introduced into Persia about

the 6th century, and continued to be played in Asia and Europe for nearly 1000 years. The powers of the pieces continued the same as in the *chaturanga*, and some of their names were preserved in a corrupted form. Thus, the piece next the king is still called in Sanscrit "*hasti*," and in the Persian "*fil*" or "*phil*," which the Western nations converted into "bishop," "fool," "leaper," "alfin," &c. Again, the piece which retains the power of the original elephant, when stationed in the corner, has the ancient name of the ship or chariot; in Sanscrit "*roka*" or "*ratha*," and in Persian "*rukh*," whence our "rook." Among the Hindus the term "ship" was changed into "war-chariot," the latter having the same importance on dry land as the ship in water. So the Persians changed the word "*roka*" into "*rukh*," which means a hero or warrior, and also a swift and fierce species of camel. From the Persians the game passed on to the Arabs, in whose language the word "*rukh*" meant the celebrated fabulous bird. So also the words "*scacchi*," "*echecs*," "*chess*," &c., are not derived from *chaturanga*, as commonly supposed, but from the Persian "*shah*" or "king," which is in use to this day among the Arabs and Persians in the same sense as our word "check." So also, when warning the king of danger, we, instead of saying "check," often use the word "king," as do the French "*au roi*;" while the Germans, with greater exactness, say "*schach*."

The board on which the *chaturanga* was played had its squares all of the same colour, nor does any change in this respect appear to have been made when the game was modified into the *shatranj*. The arrangement of the pieces in the *shatranj* was exactly as in modern chess. The king, rook, and knight moved precisely as they do now; the *farzin*, or what we now call the queen, moved only one square diagonally; the *fil*, which we call bishop, moved two squares diagonally, attacking and commanding only the square next to him but one, and he had no power over the intermediate square. When a pawn reached the opposite extremity of the board, it obtained the rank of *farzin* only, and not that of any other piece; the pawns could only advance one step at the first move, and this restriction, together with the very limited range of the queen and bishop, required some ten or twenty moves to be made on either side before the actual fight could be said to have begun. Hence, in order to save time and to prevent useless exchanges, it was agreed that the first player should make a number of moves all at once, without however crossing the middle line of the board; after which, the adversary was entitled to play up at once an equal number of counter moves, keeping however to his own half of the board. The Arabs called these preliminary moves "*Ta'biyat*," which signifies "the drawing up of troops in battle array." When Mr. Lewis visited the celebrated village of Ströbeck, near Halberstadt, he found traces of the mediæval game among the villagers. The pieces having been placed as usual, each party was obliged to play his king's rook's pawn, queen's rook's pawn, and queen's pawn two squares, and the queen to her third square. After this the other pawns could move but one square at a time. The introduction of chess into this village arose from the founding of prizes by a dignitary of the cathedral of Halberstadt, who was exiled to Ströbeck towards the end of the 15th century. His idea was, that by encouraging a game which draws so largely on the mental powers, the villagers would not be attracted by games of chance, nor injured by the vices which usually accompany them. We cannot but think that the example of the good bishop might be adopted in our own day with success.

The transition from the mediæval into the common game of the present day took place about A.D. 1500, and it consisted—first, in extending the power of the bishop, so as to allow him to command the whole diagonal instead of every third square as formerly; secondly, in conferring on the queen the enormous power of the rook and bishop combined; and lastly, in allowing the pawns to advance at the first move either one or two steps. To these improvements may be added that of casting the king, either according to the Italian method, or as now practised. The reasons for these important changes have been variously stated: we have no space for them here, but they are concisely given in Mr. Tomlinson's work. In times of chivalry a game intended to illustrate the art and science of war would be sure to receive favour, and hence chess was thought necessary to complete the education of a gentleman. Italy and Spain became celebrated not only for their players, but also for writers on the game.

The work of Cesolis, already referred to, contained no rules for playing the game. This defect was remedied in the treatises of Vicent and Lucena, published probably about 1495, and more completely in the work of Damiano, a Portuguese, in 1512. This work was written in Spanish and Italian; it contains a few openings, but the greater part of the volume consists of a collection of chess problems, many of which are still regarded as classic. In 1561, Ruy Lopez published in Spanish the 'Book of the Liberal Invention and Art of the Game of Chess.' The author was an ecclesiastic, and for some time enjoyed the reputation of being the best player in Europe; but he underwent the fate of most champions in being deposed after a brief reign. His conqueror was one Leonardo, a Calabrian, whose youthful appearance obtained for him the pseudonym of *Il Puttino*, or "the boy." Leonardo's history is romantic. After having gone through a two years' training preparatory to his contest with Ruy Lopez, he set out for Madrid, but learning that his brother had been taken by the corsairs, he determined to ransom him, and actually won

his ransom by playing chess with the captain of the galley where his brother was chained to the oar. He then proceeded to Madrid, gathering fame on his way, and beat Ruy Lopez in the presence of the Court. Among the celebrated players of the 16th century may be mentioned John Frederick of Saxony, who was playing chess when ordered for execution by Charles V. He finished his game quietly, and prepared himself for his fate: he was, however, released in 1552. Paolo Boi, of Syracuse, was also celebrated: he was considered equal to Il Puttino, and the two players were distinguished by the fanciful title of "the light and lustre of chess." Such players were accustomed to travel from court to court, and from one ducal palace to another, and the honours usually appropriated by the knights of chivalry frequently fell to their share. In 1597 appeared Gianutio's treatise at Turin. It was, however, eclipsed by Salvio's work which appeared in 1604. The games analysed therein lose in value in consequence of the Italian method of castling adopted, namely, by moving the king to his rook's square, and the rook to the king's square. The next writer of importance was Carrera, whose work appeared in 1617; it is a quarto of 600 pages, and has been translated by Mr. Lewis. In the same year Augustus, Duke of Brunswick-Luneburg, published a work under the name of Gustavus Selenus; it is a large quarto of 550 pages, and was printed at Leipzig in 1616. Greco, the Calabrian, was also known in his day as a brilliant player, and specimens of his skill are preserved in his small work, which has also been translated by Mr. Lewis. Early in the 18th century, Captain Bertin obtained fame as a chess player. He invented the opening known as the "three pawns' gambit," which, being adopted by the celebrated player Cunningham, was named by Philidor the "Cunningham gambit." Stamma, a native of Aleppo, published in 1737, a small work containing 100 end-games, many of which may still be consulted with advantage for their ingenious and brilliant play. In 1749, Philidor published in London, in French, his celebrated 'Analysis of the Game of Chess,' a work which has been reprinted or translated in almost every capital of Europe, and although it must be regarded as a compilation it is written in the most agreeable style, and contributed much to promote the practice of the game. This result was further promoted by Philidor's personal qualities, but especially by the then astounding feat of playing blindfold games, which, however useless and not so difficult as is generally imagined, is nevertheless calculated to excite the astonishment of the public. Philidor played three games without seeing any one of the boards. In our own day, a young American of the name of Morphy, has repeatedly played eight games simultaneously without seeing the boards; and another American, named Paulsen, has played twelve under similar circumstances. The marvel is, that when pitted against a number of strong players the blindfold player should be able to carry on eight separate trains of reasoning, and to preserve so much of his skill as to play stronger than his antagonists. In no case does the player play so well blindfold as over the board. Morphy's blindfold games are of a higher order than Paulsen's; so that the eight of the one are more surprising than the twelve of the other. The celebrated French player, De la Bourdonnais, who was accustomed to blindfold play, explained his method of proceeding to consist in representing in his mind the actual board and men, just as anyone may call up the features of an absent friend, so that when sitting with his eyes shut his mental vision was contemplating the shadowy figures. Now, as all persons have this faculty more or less, although one has it more strongly than another, it remains for him in whom it is most strongly developed, by cultivation and exercise, to acquire readiness in the practice. Philidor tells us how he was first led to blindfold play. When quite a lad he used to lie awake at night and play over mentally the games which he had won or lost during the day, and he soon found that he was able to run over the whole of a game, and even to introduce variations, so as to play over what are called "back games." This faculty is most useful in life, namely, the power of realising in the mind the minute details of our pursuits. Sir Isaac Newton attributed the whole of his success to this power of concentration. But to return to Philidor. In 1777, he published a second edition of his work, with considerable additions. The last and perhaps the best English translation of it is by Mr. George Walker. Philidor died in 1795, in London, of grief, on account of the French revolutionists denouncing him as a suspected character, and refusing him a passport to visit his family in Paris.

In 1750 a treatise on chess was published at Modena, and as the author concealed his name he was for many years referred to as "the anonymous Modenese." Dr. Ercole del Rio is the author, and the work has enjoyed considerable celebrity. In 1763, a laborious commentary on it was published by Lolly, and this long continued to be the great authority in chess. Coming nearer to our own day we must mention the treatises of Sarratt, Cochrane, Lewis, Walker, and others, which have had a great influence in making chess popular; but perhaps no treatises have had more influence in this respect than Mr. Staunton's 'Handbook of Chess,' and 'The Chess-player's Companion,' works which place him in the highest rank, both as a player and a writer. The most elaborate work of our own time on chess is by Jaenisch, of which there is an English translation. In concluding this part of our subject, it will be understood that we do not profess to name all the treatises on chess that have appeared, still less to give the

names of celebrated modern players. The reader will find a perfect mine of chess strategy in Mr. Walker's 'Thousand Games,' which include a large number of Philidor's games, the whole of the games in the celebrated matches between McDonnell and De la Bourdonnais, together with games by the best players in Europe, down to the date of its publication in 1844.

Practice of the game.—Conceiving that an article on chess in a Cyclopædia ought to be capable of teaching any one quite ignorant of the game, how to play, we proceed to explain its rudiments. A person in a colony or in a remote country place, into whose hands this work may fall, will thus have the means of acquiring one of the most delightful recreations that it is possible to conceive, and that without any very great amount of study or attempting to become a first-rate player.

Setting up the men.—We have already given the names and forms of the pieces, and will now arrange them in fighting order on the board, our instructions being directed to the placing of the white pieces. Place the board before you with a white square at the right-hand corner, and observe that the lines of squares running upwards are called *files*; those from left to right *ranks* or *lines*, and those which run obliquely *diagonals*. Place on the right hand corner square a white rook. Next to the rook, in the same rank, place a knight, next to the knight a bishop, next to the bishop the king, and observe that these pieces are named king's rook, king's knight, and king's bishop, respectively; but for brevity's sake they are written K. R., K. Kt., and K. B. We may here remark, that this first rank or row of squares is called, from the position of the king, *the royal line*. Next to the king place the queen, and observe that she stands on a white square, according to the old rule, that "the queen must stand on her own colour." (*Regina ad suum colorem.*) Next to the queen place a bishop, next to the bishop a knight, next to the knight a rook, and observe that these three pieces are named queen's bishop, queen's knight, and queen's rook respectively, or more briefly, Q. B., Q. Kt., and Q. R. Now before every one of these pieces place a pawn. The pawn in front of the king's rook is known as the king's rook's pawn, or K. R. P., next comes the king's knight's pawn, or K. Kt. P., next comes the king's bishop's pawn, or K. B. P., then the king's pawn, or K. P., then the queen's pawn, or Q. P., while the three remaining pawns are the queen's bishop's pawn, or Q. B. P., queen's knight's pawn, or Q. Kt. P., and the queen's rook's pawn, or Q. R. P. Now set up the black pieces on the opposite side of the board according to the same directions, making the pieces face each other, and observing that the black queen stands on a black square, and if you have accomplished your task correctly the board will present the appearance shown in the following diagram,

Diagram 2.

BLACK.

WHITE.

which represents the pieces and pawns drawn up in battle array. Next clear off the whole of the men from the board, in order to learn the names of the squares, and the method of moving the pieces. Place a rook on the right hand corner as before, and call this square the king's rook's square. The file of squares opposite to the rook, and next to the right hand edge of the board is named respectively, starting from the first square, king's rook's square, K. R. second square, K. R. third square, K. R. fourth square, K. R. fifth square, K. R. sixth square, K. R. seventh square, and K. R. eighth square. So also the square occupied by the king's knight is called the king's knight's square: the square before him occupied by K. Kt. P. is king's knight's second square: the third square in the file is K. Kt. third, and so on up to the eighth. In like manner we have king's bishop's square, K. B. second, K. B. third, and so on up to K. B. eighth. Next comes king's square, K. P. second, &c., up to K. eighth. In like manner we have queen's square, Q. B. square, Q. Kt. square, Q. R. square, in each case extending to the eighth as before. The player of the black pieces adopts the same system of nomenclature, his K. R. square is your K. R. eighth, his Q. square is your Q. eighth, your K. square is his K. eighth, Q. B. fourth square is his Q. B. fifth, his K. R. third square is your

K. R. sixth. In this simple manner all the squares on the board are appropriately named, both for the player of the white pieces and for those of the black.

The Moves.—Place a white rook on K. R. square, and observe that this piece can move in any direction parallel to the sides of the board, provided he be not obstructed by the men on either side. Standing alone on the board as he now does he may move to K. R. eighth, from K. R. eighth he may move to Q. R. eighth, thence to Q. R., thence to K. R. home again. We have thus described the longest range of the rook, his shortest range is to K. R. second, or to K. Kt.; but the rook is not compelled to make either his longest or his shortest move; he may move one, two, three, or more squares as occasion may require. Next, place the white king's bishop on his square, and the white queen's bishop also on his square, and observe that they stand on different colours; the move of the bishop is on the diagonals, thus king's bishop can move to K. R. third, thence to Q. B. eighth, thence to Q. R. sixth, and so back again to his own square. So also the queen's bishop can move to K. R. sixth, thence to K. B. eighth, thence to Q. R. third, and so back to his own square. Or he may move one, or two, or three, or more squares according to circumstances. Observe that the king's bishop always moves on the white diagonals, and that the queen's bishop always keeps to the black, so that the two bishops never interfere with each other's actions. But the white king's bishop moves on the same colour as the black queen's bishop, and the white queen's bishop moves on the same diagonals as the black king's bishop, and consequently can be attacked or captured the one by the other. Next place the queen on her own square: her move combines the moves of the rook and the bishop respectively: this tremendous power is supposed to have been conferred during the chivalrous age, as a tribute to the fair sex, and it was not uncommon to call the Persian Farzin, or counsellor, *Fearce* or *Fierge*, which by an easy change passed into *Vièrge*, or the "Virgin;" but the gallantry which conferred on this piece the title of queen, introduced an anomaly into the game, for not only is it unnatural to make a woman the most destructive of warriors; but it is still more so to promote a pawn or foot soldier to the rank of queen, as a reward for having penetrated the enemy's ranks and got to the eighth square. It is not necessary to give any directions respecting the moves of the queen, since we know those of the rook and of the bishop. Place the king on the K. square: his move consists of the shortest move of the queen; that is, he can from his own square move to K. second square, or to Q. second square, or to Q. square, or to K. B. square, or to K. B. second square. At any part of the board where he may happen to be he can thus move one square forwards or backwards to the right or to the left, or upon any one of the four diagonals which surround him; subject, however, to this remarkable condition, that he never approach the opposite king, but always be separated from him by at least one square. The reason for this depends on the fundamental principle of chess, namely, that the person of the king is sacred, and as he can never be captured, so he can never put himself under attack, or "in check" as it is called, which he would do if he occupied the next square to his royal adversary. As the kings cannot attack each other, or remain under attack from any of the pieces or pawns, it is customary to warn your adversary when you attack his king, by calling out "check," and should he be unable to escape the attack, or "get out of check," as it is called, the game is at an end. We now come to describe the knight's move. Place king's knight on his square, and queen's knight also on his square. The move of the knight is curious, it consists of the shortest move of the rook and the shortest move of the bishop, both together; thus, if we play the knight to Kt. second, he can then be moved forward either to K. R. third, or K. B. third; so also the queen's knight taking the shortest move of the bishop can be moved to Q. R. second, and then the shortest move of the rook forwards will take it to Q. R. third. The knight of course gains power when removed from the sides of the board; when king's knight stands at home he can be played to three squares only, namely, to K. R. third, to K. second, or to K. B. third; but when the knight is on K. B. third, or on any other square away from the sides, it will be seen that he can be played to any one of eight squares, so that he is said to "command" these eight squares, and can capture one of the enemy's pieces or pawns placed thereon. The Knight possesses the peculiar privilege of leaping over the other pieces. The pawns have the power of moving one or two steps forwards at pleasure at the first move, thus the king's pawn which stands at K. second, can be moved either to K. third, or to K. fourth, after which it moves one step at a time along its own file, except when it captures, when it moves one step diagonally forwards either to the right or to the left; for example, suppose black have a pawn at his K. fourth, another at his Q. fourth, and a third at his K. B. fourth, and that you have a pawn at your K. fourth; if you have to move you cannot advance the pawn forwards on the king's file, because the path is obstructed by the black pawn at your adversary's K. fourth, but you can capture either his queen's pawn or his king's bishop's pawn, by removing it from the board and placing your own pawn there in its stead: thus the pawns may change their files in advancing forwards, in capturing, but unlike the pieces they have no power to move backwards.

There is a curious condition attached to the privilege of moving the pawn two steps forward at the first move, namely, the power of capturing such pawn by your adversary, provided he have a pawn advanced

to his fifth square on one of the adjacent files; for example, suppose black to have a pawn on his Q. fifth square, and your king's pawn has not yet been moved, if you move the pawn one square, namely, to K. third, it is obvious that the black pawn can capture it. If you play the pawn two steps instead of one, the black pawn can equally capture it, by taking the pawn from the board and playing to K. sixth just as if the white pawn had only moved one step. This is called taking a pawn *en passant*. It is quite optional on the part of the player whose pawn is passed; but if he does not take the pawn, *en passant*, at his next move, he forfeits the privilege, and the two steps taken by the pawn are allowed.

Such are the moves or powers of the pieces. Attempts have been made to express them numerically; taking the pawn as unity, or 1·00, the knight is equal to 3·05, the bishop 3·50, the rook 5·48, the queen 9·94. These numbers must of course vary at different parts of the game. When the board is prepared for play, as in diagram 2, the knights alone, from their leaping power, have value; all the other pieces are blocked in by the pawns, and it is the function of good chess play so to move the pawns as to develop gradually the powers of the pieces. Tables of the respective values of the pieces have been calculated at different points of the game, as in moving over the open board, —in moving over the board when about half cleared by play, &c. Other calculations refer to their values in keeping off the antagonist from a particular set of squares, or in making an attack on two or more different squares, or in dislodging an antagonist from a particular square, or in giving mate without the aid of other pieces, &c. These various tables being collected together, and the mean taken for each piece, we get the average numbers as above. As the king can never be exchanged or captured, he is excluded from the list. It will thus be seen that the knight is worth about three pawns; and that a rook is worth a bishop and two pawns, or five pawns and a half. There appears to be a difference of nearly half a pawn between a bishop and a knight, although in practice a player will exchange one for the other; but in an average state of the board, the bishop can attack the knight in a smaller number of moves than the knight can attack the bishop, and this gives an increased value to the bishop. The bishop and knight are called *minor* pieces, and when a player wins these two for one of his rooks, he is said to "win the exchange."

Before concluding this part of our subject we will give the reader an exercise on the knight's move. It is one of the numerous solutions of the celebrated problem, "to name two different squares on the chess-board of different colours, and placing a knight on one of them, to require him to leap on every square of the board, and to finish his leaps on the other square without stepping twice upon any one square; or, as it is more consisely expressed, "to cover the board with the Kt. in sixty-four moves." This problem has engaged the attention of many distinguished mathematicians, such as Euler, Bernoulli, Mairan, Demoivre, Willis, and Dr. Roget. The last gentleman has discovered a general solution of the problem. ('Philosophical Magazine,' 1840.) An abstract of it, together with other particulars respecting the problem, is given in Mr. Tomlinson's 'Amusements in Chess.'

Diagram 3.

The Game.—We will now play over one of Greco's games, in order to exercise the reader in the moves of the pieces, and in the nomenclature of chess. We shall continue to give instructions to the player of the white pieces, so that the reader will have the board before him, with the men arranged as in diagram 2.

WHITE.

BLACK.

1. P. to K. fourth square.

1. P. to K. fourth square.

This is the best move on both sides, since it liberates two pieces: namely, the Queen, who has a range of a diagonal of four squares: and K. B., who has a range of one of five; since it is generally found that the player who commands the largest number of squares has the greatest power. After this preliminary move on both sides, you have various methods of opening the game, but we will select what is called the King's Knight's game.

2. K. Kt. to K. B. third.

In this position your knight attacks the black K. P., and black has various modes of defending it; he may do so by playing K. B. to Q. third,

but this would be a bad move, because it prevents Q. P. from moving, and shuts in Q. B. Secondly, he may defend it by playing P. to Q. third; but that shuts in the K. B., although this is less objectionable than in the former case. Thirdly, he may play Q. to K. second, but this more effectually shuts in the K. B. Fourthly, he may defend K. P. by playing P. to K. B. third; but this is a bad move, as we shall see hereafter. Fifthly, he may defend the pawn by Q. Kt. to Q. B. third, which is perhaps his best move.

2. Q. Kt. to Q. B. third.

3. K. B. to Q. B. fourth.

This is a good place for the bishop, since it attacks the weakest point in your adversary's game, namely, his K. B. P., which is defended only by the king.

3. K. B. to Q. B. fourth.

This is a good move on the part of black, for similar reasons.

4. P. to Q. B. third.

This move is to enable you [to advance P. to Q. fourth at the next move, which is a very good mode of continuing the attack.

4. Q. to K. second.

This prevents you from playing the move intended, since he would capture your Q. P. with his K. P., whereby your K. P. would be liable to be taken by his Q.; you therefore castle.

5. Castles.

This operation is performed by playing K. R. to K. B. square, and moving the K. to Kt. square. This privilege of moving two pieces at once, and making the king move over two squares, can occur only once on each side during the game. The advantage of it is that you thus place your king in safety, and liberate your rook. There are several conditions attached to castling, which will be noticed hereafter.

5. P. to Q. third.

This further defends the K. P. and liberates the Q. B.

6. P. to Q. fourth.

6. K. B. to Q. Kt. third.

Black prefers to withdraw his bishop to capturing your Q. P. with his K. P.

7. Q. B. to K. Kt. fifth.

The bishop thus attacks the black Q., and she cannot capture him without being retaken by your K. Kt.

7. P. to K. B. third.

Black thus interposes a pawn between the attack of the bishop. It would have been better for him to have interposed K. Kt.; this would have enabled him to castle, with the additional advantage of having brought out another piece. His K. B. P. now attacks your Q. B., and you therefore make him retreat.

8. Q. B. to K. R. fourth.

8. P. to K. Kt. fourth.

Black advances this pawn upon your bishop, thinking to make him retreat to K. Kt. third, but now occurs one of Greco's brilliant strokes of play.

9. K. Kt. takes K. Kt. P.

You remove the black K. Kt. P. from the board, and place your K. Kt. in its stead.

9. P. takes K. Kt.

Black has thus gained a knight for a pawn, and holds the bishop *en prise*, as we say when a piece is liable to be captured by one of the enemy's forces.

10. Q. to K. R. fifth, checking.

You leave your bishop *en prise*, and make an attack on the black king with your queen. Whenever the king is thus threatened, either by a piece or a pawn, you must call out "check," and the game cannot proceed until the king gets out of check. This may be done in one of three ways; *first*, by interposing a piece or pawn; *secondly*, by capturing the attacking piece; or *thirdly*, by moving the king. In the case before us, the only piece that can be interposed is the black queen; but this would render her liable to be captured, either by your Q. or by your K. B. He cannot capture your Q., so that he must move his king.

10. K. to Q. second.

11. Q. B. takes P.

You may now capture the pawn, attacking his Q. with your B. The black Q. escapes from this attack by playing

11. Q. to K. Kt. second.

12. K. B. to K. sixth, checking.

This is another brilliant sacrifice. The king must capture your bishop, since he has no other method of getting out of check.

12. K. takes K. B.

13. Q. to K. eighth, checking.

In this case, the only method of escaping check is by interposing a piece.

13. K. Kt. to K. second.

14. P. to Q. fifth, checkmate.

This finishes the game; for although your Q. is *en prise* to his K. R. and your Q. B. to his Q., these pieces are in no danger so long as his K. is in check; and as he cannot get out of check, he is said to be "check-mated."

This style of play reminds us of some complimentary lines addressed to Greco, in the *Mercur Galant*, for June, 1683:—

"A peine dans la carrière
Contre moi tu fais un pas,
Que par ta démarche fière
Tous mes projets sont à bas :
Je vois dès que tu t'avances,
Céder toutes mes défenses,
Tomber tous mes champions ;
Dans ma résistance vaine,
Roi, Chevalier, Roc et Reyne,
Sont moindre que tes Pions."

Laws of the Game.—The reader is now in a condition to study what are called the "Laws of the Game." These include institutes and definitions, as well as laws; but as they were revised some years ago by the London Chess Club, and adopted by the other clubs, both in this country and abroad, and authoritatively inserted in Mr. Staunton's 'Handbook of Chess,' we give them with only such alterations as appear to us to be necessary to correct the sense and the grammar. Our alterations are printed in italics. There are several points in which these laws are defective and tautological; Jaenisch and Heydebrand have published treatises in which their anomalies are elaborately discussed, and suggestions made for their revision and improvement. On these suggestions Staunton drew up a new code of laws, which he submitted to the British Chess Association at the close of its meeting at Leamington, in 1855. The meeting appointed a committee to discuss the matter with Mr. Staunton, and present their report, containing a copy of the new laws, to Lord Lyttleton, at the next annual meeting of the Association. The committee, consisting of Rev. W. Wayte, and Messrs. Löwenthal, Ingleby, and Tomlinson, met several times at the St. George's Chess Club, London, and agreed on their report, but it has not yet appeared.

THE LAWS OF CHESS.

I. The Chess-board must be so placed that each player have a white corner square nearest his right hand. If the board have been improperly placed, it must be adjusted, provided *four* moves on each side have not been played, but not afterwards.

II. If a piece or pawn be misplaced at the beginning of the game, either player may insist upon the mistake being rectified, if he discover it before playing his fourth move, but not afterwards.

III. Should a player at the commencement of the game omit to place all his men on the board, he may correct the omission before playing his fourth move, but not afterwards.

IV. If a player, undertaking to give the odds of a piece or pawn, neglect to remove it from the board, his adversary, after four moves have been played on each side, has the choice of proceeding with, or recommencing the game.

V. When no odds are given, the players must take the first move of each game alternately, drawing lots to determine who shall begin the first game. If a game be drawn, the player who began it has the first move of * the following one.

VI. The player who gives the odds has the right of moving first in each game, unless otherwise agreed. Whenever a pawn is given, it is understood to be always the King's Bishop's Pawn.

VII. A piece or pawn touched must be played, unless, at the moment of touching it, the player say "*J'adoube*," or words to that effect; but if a piece or pawn be displaced or overturned by accident, it may be restored to its place.

VIII. While a player holds the piece or pawn he has touched, he may play it to any other than the square he took it from, but having quitted it, he cannot recall the move.

IX. Should a player *touch*† one of his adversary's pieces or pawns, without saying "*J'adoube*," or words to that effect, his adversary may compel him to take it; but if it cannot be legally taken, he may oblige him to move the King; should his King, however, be so posted that he cannot be legally moved, no penalty can be inflicted.

X. Should a player move one of his adversary's men, his antagonist has the option of compelling him to *do one of three things*—1st, to replace the piece or pawn and move his *own* King; 2nd, to replace the piece or pawn and take it; 3rd, to let the piece or pawn remain on the square to which it had been played, as if the move were correct.

XI. If a player take one of his adversary's men with one of his own that cannot take it without making a false move, his antagonist has the option of compelling him to take it with a piece or pawn that can legally take it, or to move his own piece or pawn which he touched.

XII. Should a player take one of his own men with another, his adversary has the option of obliging him to move either of *them*.

XIII. If a player make a false move, that is, play a piece or pawn to any square to which it cannot legally be moved, his adversary has the choice of *one of three* penalties: namely, 1st, of compelling him to let the piece or pawn remain on the square to which he played it; 2nd, to

* Staunton has *or*.

† Staunton has *take*.

move it correctly to another square; 3rd, to replace the piece or pawn and move his King.

XIV. Should a player move out of his turn, his adversary may choose whether both moves shall remain, or the second be retracted.

XV. When a pawn is first moved in a game, it may be played one or two squares; but in the latter case the opponent has the privilege of taking it *en passant* with any pawn which could have taken it had it been played one square only. A pawn cannot be taken *en passant* by a piece.

XVI. A player cannot castle in the following cases:—

1. If the King or Rook have been moved.
2. If the King be in check.
3. If there be any piece between the King and the Rook.

4. If the King pass over any square that is attacked by one of the adversary's pieces or pawns.

Should a player castle in any of the above cases, his adversary has the choice of one of three penalties, namely, 1st, of insisting that the move remain; 2nd, of compelling him to move the King; 3rd, of compelling him to move the Rook.

XVII. If a player touch a piece or a pawn that cannot be moved without leaving the King in check, he must replace the piece or pawn and move his King; but if the King cannot be moved, no penalty can be inflicted.

XVIII. If a player attack the adverse King without saying "Check," his adversary is not obliged to attend to it; but if the former, in playing his next move, were to say "Check," each player must retract his last move, and he that is under check must obviate it.

XIX. If the King have been in check for several moves, and it cannot be ascertained how it occurred, the player whose King is in check must retract his last move, and free his King from the check; but if the moves made subsequent to the check be known, they must be retracted.

XX. Should a player say "Check," without giving it, and his adversary in consequence move his King, or touch a piece or pawn in order to interpose it, he may retract such move, provided his adversary have not completed his next move.

XXI. Every pawn which has reached the eighth or last square of the chess-board must be immediately exchanged for a Queen or any other piece the player may think fit, even though all the pieces remain on the board. It follows therefore that he may have two or more Queens, three or more Rooks, Bishops, or Knights, at the same time on the board.

XXII. If a player remain at the end of the game with a Rook and a Bishop against a Rook, with both Bishops only, with Knight and Bishop only, &c., he must check-mate his adversary in fifty moves on each side at most, or the game will be considered as drawn; the fifty moves to commence from the time when the adversary gives notice that he will count them. This law holds good for all other check-mates of pieces only, such as Queen or Rook only, Queen against a Rook, &c., &c.

XXIII. If a player agree to checkmate with a particular piece or pawn, or on a particular square, or engage to force his adversary to stale-mate or check-mate him, he is not restricted to any number of moves.

XXIV. A stale-mate is a drawn game.

XXV. If a player make a false move, castle improperly, &c., &c., the adversary must take notice of such irregularity before he touches a piece or pawn, or he will not be allowed to inflict any penalty.

XXVI. Should any question arise, respecting which there is no law, or in case of a dispute respecting any law, the players must refer the point to the most skilful disinterested bystanders, and their decision must be considered as conclusive.

Remarks.—There are a few points respecting these laws which call for notice. It will be seen that in actual play the chessmen are not to be touched except to be played, unless for the purpose of re-adjusting a man on his proper square, when you must signify your intention by saying *J'adoube*, or "I adjust." The laws which regulate what is called the *strict game*, are of great importance to be attended to; for it is impossible to become a chess-player except by playing slowly and never taking back a move. We have some faith in the "morals of chess," and believe, that when properly played, the game exercises caution, forethought, and perseverance; but all these qualities are lost sight of if a player be allowed to pull about the pieces mechanically, instead of mentally calculating his move, and making it when he has decided on it. There are many drawing-room players who object to take odds of a superior player, but nevertheless do not hesitate to take back moves, not considering that this is odds, and very large odds too. We often meet with players who look with mild astonishment when you take a pawn *en passant*, or queen a pawn when you have already a queen on the board; or castle when your rook is under attack; or when you declare the game to be drawn by a stale-mate, or by your adversary's persisting in playing when there is not sufficient mating-force on the board, &c. A few remarks on these points may be useful. With respect to pawn takes pawn, *en passant*, an example of the practice by one of our great chess-authorities will be decisive. The following short game is a good example of Mr. Cochrane's brilliant

* Staunton has lost.

style of attack, and it will be seen that the game is won off-hand, or forced as it is called, in consequence of the privilege in question:—

WHITE, Mr. C.

1. P. to K. 4.
2. K. Kt. to K. B. 3.
3. K. B. to Q. B. 4.
4. P. to Q. B. 3.
5. P. to K. 4.
6. P. to K. 5.
7. K. B. to Q. 5.
8. K. B. takes K. B. P. (ch.)
9. K. Kt. to Kt. 5, (ch.)
10. Q. to Q. Kt. 3, (ch.)
11. K. P. takes Q. P. *en passant*. (ch.)
12. Q. takes B. (ch.)
13. Q. mates.

BLACK.

1. P. to K. 4.
2. Q. Kt. to Q. B. 3.
3. K. B. to Q. B. 4.
4. K. Kt. to K. B. 3.
5. P. takes P.
6. K. Kt. to K. 5.
7. K. Kt. takes K. B. P.
8. K. takes B.
9. K. to Kt.
10. P. to Q. 4.
11. Q. B. to K. 3.
12. K. to B.

With respect to two queens, three bishops, &c. on the board at the same time, a notion prevails that when a pawn arrives at its eighth square, you can only claim in exchange for it, one of the pieces you have lost. In the following position by Kling (*Diagram 4*), White has a

Diagram 4.

pawn at his Q. seventh. Now it is curious that, supposing White to have the move, he can mate in a fewer number of moves by queening the pawn and exchanging it for a knight than by exchanging it for a queen. Having made this move, he thus has three knights on the board which mutually protect each other. Black has now to play, and he has but one move, namely K. to Q. third, whereupon you play R. to Q. R. seventh. Black's only move is K. to Q. fourth, and you mate next move with the rook. In the next position (*Diagram 5*), also by

Diagram 5.

Kling, if you queen the pawn and exchange it for a queen, you stale-mate your adversary, for he has no move except to place himself in check, which by the laws of the game he is not allowed to do; but if in queening your pawn you claim a bishop, you can check-mate him next move. Now it does seem a great anomaly that you can have a very different force, different not only in amount but in kind, at the end of the game to what you have at the beginning, such as three knights, or as in the present case two bishops, both running on black

diagonals. The very expression too, *queening a pawn*, is ambiguous; for the term is still made to apply, even though you exchange the pawn for a rook or a *minor piece*, as the bishop or the knight is called.

With respect to castling, Law xvi. defines the conditions under which that privilege can be exercised. Many players suppose that you cannot castle if the king has been checked, or if the rook is attacked. Now although it is quite true that you cannot castle out of check, it does not matter how many times your king may have been checked, provided he has not been moved. So also, with respect to the rook, you cannot castle if it has been moved, but you can castle, even though it be *en prise*, as in the following brilliant little game, in which Captain Kennedy gives the odds of his king's knight to the player of the black pieces; so that in setting up the board for this game you will remember to take off the white K. Kt.

WHITE, Capt. K.

1. P. to K. 4.
2. K. B. to Q. B. 4,
3. P. to Q. 4.

BLACK.

1. P. to K. 4.
2. K. Kt. to K. B. 3.
3. Kt. takes K. P.

Black at his third move should have played Pawn takes Pawn.

4. Q. P. takes P.

4. Kt. K. B. P.

Black intends the white king to take his Kt., whereupon he would check with his Q. at K. R. fifth, and recover the piece.

5. Castles.

It will be seen that White can castle, even though his rook be *en prise*. The move, however, is unexpected, because White leaves his queen *en prise*, and the young player snaps it up and loses the game in a couple of moves by a well known mate.

6. K. B. takes K. B. P. (ch.)
7. Q. B. to K. Kt. 5. (ch.-mate.)

5. Kt. takes Q.
6. K. to K. 2.

We reserve the point respecting stale-mate until we come to speak of the varieties of check-mate. A game is *drawn*, that is, not won by either player, under various circumstances: first, the position may be so locked that there is nothing to do but to repeat the same moves backwards and forwards, since any deviation would entail loss: or secondly, there may not be sufficient mating force on the board, as when the kings are left with locked pawns, and the bishops are of *opposite colours* as they are called, when, for example, the white bishop moves on black diagonals, and the black bishop on white ones; or thirdly, when one player who fears to lose the game, may have it in his power to check the king every move, and should he persist in doing so, he draws the game by what is called a *perpetual check*. The following is an example of this kind (*Diagram 6*), in a game between Philidor and

Diagram 6.

WHITE.

Bowdler, in which Philidor gives the odds of the pawn and two moves; and although he has just *won the exchange*, that is, two minor pieces for a rook, Black has two *passed pawns*, that is, pawns that have *passed*, or escaped the attacks of other pawns, and in moving to queen, can only be opposed by the adversary's pieces. Philidor, therefore, having the move, seeks to break up this formidable array of pawns, by first capturing the black K. B. P. with his K. B., whereupon Black *pins* the bishop by playing R. to K. B. 3., and White now seizes the opportunity of drawing the game by a perpetual check. He plays R. to Q. R. eighth, checking; black king goes to king's bishop seventh; white checks again at Q. R. seventh; king moves to K. B. square; rook checks again, and king goes to K. Kt. second square: White checks again, and K. goes back to B. square, and both parties persisting in this line of play, the game is drawn; for should White seek to

escape the check by playing to K. R.'s square, he would be mated on the move. The following is another perpetual, also from Philidor

Diagram 7.

WHITE.

(*Diagram 7*), in which that great master has again the worst of the game, Black having a passed pawn, and threatening to take off the Q. P. with his Kt., and thus have another passed pawn. Instead of defending his Q. P. with his R., he plays R. to Kt. seventh, checking, whereupon Black inconsiderately plays his K. to Q. B. third, White takes Q. R. P. with his Kt., checking. King has only one square to move to, namely, Q. third, whereupon Kt. checks again and so on perpetually.

Check-mate.—The object of the game of chess is to check-mate your adversary in the fewest possible number of moves. It would be considered bad play in any given position of the pieces with a mate on the board, to finish the game in four moves when it could be accomplished in three. The average length of a game is about thirty moves on each side; but we have known a game extend to ninety or a hundred moves on each side. With very bad play on the part of your adversary, mate may be given in two moves: this is known as the "*Fool's Mate*," and is as follows:—

WHITE.

1. P. to K. B. 4.
2. P. to K. Kt. 4.

BLACK.

1. P. to K. 3.
2. Q. to K. R. 5, Check-mating.

This is the shortest possible game of chess. The next shortest game is known as the "*Scholar's Mate*." It is as follows:—

WHITE.

1. P. to K. 4.
2. K. B. to Q. B. 4.
3. Q. to K. R. 5.
4. Q. takes K. B. P., check-mating.

BLACK.

1. P. to K. 4.
2. K. B. to Q. B. 4.
3. P. to Q. 3.

There is a peculiar kind of mate given by the knight, known as the "*Smothered Mate*;" it is also sometimes called "*Philidor's Legacy*," from a position left by that great master. The following (*Diagram 8*)

Diagram 8.

WHITE.

will illustrate it, together with the peculiar powers of the knight in attacking a number of pieces at the same time. Supposing White to have the move, he plays knight to K. B. seventh, checking, and at the

same time *forking*, as it is called king, queen, and two rooks. The black king can only get out of check by moving to Kt. square, whereupon the knight takes rook at K. R. third with a *double check*, for he not only checks with the knight, but discovers check with the queen. There is but one method of escaping from a double check, and that is by moving the king. In the present case the king cannot move to his K. B. square, on account of the position of your rook at K. B. square; he must therefore go back into the corner, whereupon you play your queen to K. Kt. eighth, checking; Black must take your queen with his rook, whereupon knight goes to K. B. seventh, giving a smothered mate.

Stale-mate.—Another description of mate is the "Stale Mate." It occurs when the king, not being in check, cannot move without moving into check, and has no other piece or pawn which can be moved. This

Diagram 9.

makes what is called a drawn game, neither party winning. There are, as already remarked, several modes of drawing the game, and this is one of them. A skilful player, whose game appears to be hopelessly lost, will sometimes try after a stale, and cleverly effect his object to the great annoyance of his adversary. The above position (Diagram 9), given by Sarratt, is a case in point. In this position it seems impossible for White to save the game, since Black threatens to check with the queen and to mate at K. R. seventh; but it is a matter of great importance at chess who has *the move*. In the present case White has the move, and he plays as follows:—

- | WHITE. | BLACK. |
|------------------------|-------------------|
| 1. R. to K. B. 8 (ch.) | 1. K. to Q. R. 2. |
| 2. R. to Q. R. 8 (ch.) | 2. K. takes R. |
| 3. Q. to K. B. 8 (ch.) | 3. K. to Q. R. 2. |
| 4. Q. to Q. B. 5 (ch.) | |

If Black move his king back to Q. R. square, you again check with your queen at K. B. eighth, and draw the game by a perpetual check. If he interpose queen's knight's pawn you capture his queen's bishop's pawn, and again draw by a perpetual check. You cannot, of course, capture his queen, on account of the threatened mate with his rook. If he capture your queen you are stale mated, because the king not being in check, cannot move without moving into check.

There is another solution to this problem, by which the moves of the Black are so far forced, that he loses the game unless he consent to draw by stale mate.

- | WHITE. | BLACK. |
|----------------------------|----------------------|
| 1. R. to K. B. 8 (ch.) | 1. K. to Q. R. 2. |
| 2. Q. to Q. B. 5 (ch.) | 2. Q. takes Q. |
| 3. R. to Q. R. 8 (ch.) | 3. K. to Q. Kt. 3. |
| 4. R. takes Q. R. P. (ch.) | 4. K. or P. takes R. |
| 5. is stale mated. | |

If at the third move Black take rook, White is stale-mated in a fewer number of moves.

According to the laws of the game, a stale-mate is a drawn game. It is also optional whether a player take a pawn *en passant* or not. A curious point was discussed by some members of the laws' committee, already referred to, as to whether in order to escape a stale-mate, a player could be compelled to take a pawn *en passant*. For example, in the following position (Diagram 10), suppose White to play pawn to K. Kt. fourth square, Black would be stale-mated unless he took the pawn *en passant*. It was contended that you could not compel an act which was purely voluntary, since it is expressly provided that while a player may advance his pawn two steps at the first move, it is optional whether the second player allow the *passar bataglia*, as the Italians call it, and that it would be contrary to the principles of chess to determine otherwise. On the other hand, it was contended by Mr. Tomlinson that so long as the stale-mate is defined to be "a position in which the

king, not being in check, cannot move without passing into check, and there is no other possible move on the board," the voluntary nature of the *passar bataglia* becomes changed into a *compulsory*, because a *possible* move. In such a position as the following (Diagram 10), it

Diagram 10.

would be very anomalous if Black were to be allowed a stale-mate when he has it in his power to move one of his pawns.

The Openings.—The various modes of opening the game are: 1. *The King's Knight's game*; 2. *The King's Bishop's game*; 3. *The Queen's Bishop's Pawn's game*; 4. *The King's Gambit*; 5. *The Queen's Gambit*. Each of these openings has a number of varieties, many of which have also their distinctive names. Most of them are known as *regular* openings, to distinguish them from a rather large class which may be collected together into, 6. *Miscellaneous* or *irregular* openings. Games in any opening are called *open*, when each player plays at his first move Pawn to K. fourth square; whereas those games are called *close*, in which one or both of the players play at his first move Pawn to K. third square; or the second player, in answer to Pawn to K. fourth square, moves his queen's bishop's pawn to his fourth square, forming what is called the *Sicilian Game*.

We will give a few games illustrative of the openings, and their principal varieties. Our examples will consist of actual games by first-rate players. We shall not trouble the reader with many explanatory notes, as he will be able in most cases by careful study to discover for himself the beauties and peculiarities of each master.

The following is an example of that variety of the King's Knight's game, called by the Italian masters the *Gioco Piano*, a term which we have adopted; games of this kind being also called *Piano* games. We do not indicate the colours, since it is desirable to be able to play either with the white pieces or with the black. If the student is accustomed to play only with white men, he will do well to take the black pieces in playing over these games.

The following is a variety of King's Knight's opening, known as the *Scotch opening*, from the circumstance of its having been adopted in the match by correspondence between the clubs of London and Edinburgh; it is also known as the *Queen's Pawn two opening*, and the *Central Gambit*. The opening is however to be found in Lolli.

21. Resigns.

The following variety of the Knight's opening is known as the *Evans' Gambit*, from the name of the inventor, Captain Evans, R.N. It consists in the sacrifice of the queen's knight's pawn at the fourth move of the first player, thereby enabling him to establish his pawns in the centre, and to attack the adversary's king with his queen and queen's bishop. We may here remark that the word *gambit* is from the Italian *giambetto*, a term used in wrestling where by a peculiar turn of the leg the adversary is overthrown. There are many forms of gambit at chess, and in every one there is the sacrifice of a pawn early in the game; this being the trick by which a powerful attack is gained. In the following game the Indian chess player, Shagird, gives the odds of the queen's knight, so that in setting up the pieces be careful to remove the first player's queen's knight.

23. K. to B. 2.

We now come to the regular gambits which produce some of the most brilliant and complicated positions in chess. In the *King's Gambit* the first player sacrifices his king's bishop's pawn at the second move, for the sake of a good attacking position. The second player may safely capture the proffered pawn with his king's pawn, and defend the *gambit pawn** against any attack. This extra pawn ought, with good play, eventually to lead to a won, or at least a drawn, game; but the variety of attack, and the difficulty of correct defence are so great, that even among the best players the gambit is frequently adopted. Although so much has been written on the subject by chess analysts, yet new forms of attack and defence appear every year, so inexhaustible is the variety afforded by the royal game. The following is an example of the *King's Knight's Gambit*, in which the king's knight is brought out at the third move, to distinguish it from the *King's Bishop's Gambit*, in which the king's bishop is so played. Another variety of the king's gambit is the *King's Rook's Pawn's Gambit*, in which the king's rook's pawn is played at the third move. There is also the *Muzio Gambit*, the *Allgaier gambit*, the *Cunningham gambit*, &c. Our first example is of the *King's Knight's Gambit* between two celebrated players:—

VON DER LAZA.

12. P. takes B. (disc. ch.)
13. Kt. to K. 5.
14. P. to Q. B. 3.
15. Q. to K. 4.
16. Q. takes R.

10. P. to K. Kt. 5.
11. B. takes Kt.
12. K. to Q.
13. R. to R. 2.
14. P. to K. B. 6.
15. K. Kt. to B. 3.
16. Kt. takes Q.

The first player now commenced a forced mate in six moves, namely, 17. Kt. takes P. (ch.); 18. R. to K. (ch.); 19. Q. B. takes P. (ch.); 20. R. to K. 8 (ch.); 21. R. takes Kt. (ch.); 22. K. B. to Q. 3, mate. The moves of the black K. are all forced.

The following variety of the King's Gambit is known as the *Muzio gambit*. In it the second player, at his fourth move, pushes the pawn on his adversary's king's knight, which is allowed to be captured for the sake of the attack which is thus gained:—

M'DONNELL.

1. P. to K. 4.
2. P. to K. B. 4.
3. K. Kt. to K. B. 3.
4. B. to Q. B. 4.

23. Q. to K. 5.
24. K. B. to K. 2.
25. K. to B. 2†
26. Q. B. to K. 3.
27. P. to K. R. 4.
28. Q. to Q. 5.
29. K. takes P.
30. K. to Q. 2.
31. Resigns.

DE LA BOURDONNAIS.

1. P. to K. 4.
2. P. takes P.
3. Q. to K. R. 5 (ch.)
4. P. to K. Kt. 4.
5. K. B. to Kt. 2.
6. Kt. to Q. B. 3.
7. K. Kt. to K. 2.
8. Q. to K. R. 4.
9. P. to K. R. 3.
10. B. takes Kt.
11. P. to Q. 4.
12. K. Kt. to B. 4.
13. K. to Q.
14. K. Kt. takes Q. P.*
15. Q. Kt. takes Kt.
16. Kt. to Q. B. 3.
17. K. to K.
18. Q. B. to K. 3.
19. K. to K. B.
20. K. to Kt.
21. Q. to K. Kt. 3.
22. P. to Q. B. 4.
23. Q. R. to K.
24. P. to K. B. 6.
25. P. takes B.
26. P. to Q. Kt. 3.
27. Q. B. to Q. 2.
28. Q. takes P. (ch.)
29. B. to K. Kt. 5 (ch.)
30. R. to Q.

* If he check with Kt. and capture R., he is mated. For example:—

- | | |
|-----------------------------|---------------------------|
| 15. K. to Kt. (best.) | 14. Kt. to K. Kt. 6 (ch.) |
| 16. Kt. takes Kt. (ch.) | 15. Kt. takes R. |
| 17. Kt. to Q. Kt. 8 (ch.) | 16. K. to Q. 2 (best.) |
| 18. K. B. to Q. Kt. 5 (ch.) | 17. R. takes Kt. |
| 19. Q. to K. 7 (mate). | 18. P. to Q. B. 3. |

† Capturing the P. would evidently cost him his Q.

BUDZINSKY.

1. P. to K. 4.
2. P. to K. B. 4.
3. K. B. to Q. B. 4.
4. K. B. takes P.
5. Kt. to Q. B. 3.
6. P. to Q. 3.
7. P. takes Kt.
8. Q. to K. B. 3.
9. Kt. to K. 2.
10. P. takes B.
11. P. to Kt. 3.

MORPHY.

1. P. to K. 4.
2. P. takes P.
3. P. to Q. 4.
4. Kt. to K. B. 3.
5. B. to Q. Kt. 5.
6. Kt. takes B.
7. Castles.
8. R. to K. (ch.)
9. B. takes Kt. (ch.)
10. Q. to K. R. 5 (ch.)
11. B. to K. Kt. 5, winning a piece.

As a general rule it is always best to accept the gambit when it is offered. The following little game from Greco is a specimen of what is called the *Gambit refused* :—

1. P. to K. 4.
2. P. to K. B. 4.
3. K. P. takes Q. P.
4. Q. Kt. to Q. B. 3.
5. K. Kt. to K. B. 3.
6. K. to B. 2.
7. P. to Q. 4.
8. K. B. to Q. Kt. 5 (ch.)
9. K. R. to K.
10. K. R. to K. 8, checkmate.

1. P. to K. 4.
2. P. to Q. 4.
3. Q. takes P.
4. Q. to K. 3.
5. P. takes P. (disc. check.)
6. K. B. to Q. B. 4 (ch.)
7. K. B. to Q. 3.
8. K. to Q.
9. Q. to K. B. 4.

The *Queen's Gambit* is a very different opening from the king's. It is not so brilliant nor so varied, and the gambit pawn cannot be defended with safety. De la Bourdonnais was a master in this opening, and the following is a fine specimen of one of the games in his celebrated contest with M'Donnell :—

DE LA BOURDONNAIS.

1. P. to Q. 4.
2. P. to Q. B. 4.
3. P. to K. 4.
4. P. to Q. 5.
5. Q. Kt. to Q. B. 3.

35. K. R. to K. 2.
36. K. to Kt. 3, and wins.

The foregoing specimens will serve to illustrate something of the wonderful variety and beauty of chess. There are many other openings which in a longer article might be selected, together with games by Löwenthal, Horwitz, Harrwitz, Brien, and many other living players. We might also show the skill of first-rate men in giving the odds of rook, knight, or bishop; but as in such cases any of the regular openings may be played, it is the less necessary to do so, especially as we have already given one or two games at the odds of the knight. The odds of the pawn and move, or pawn and two moves, is however peculiar, and requires some illustration. When a strong player is unable to give his opponent a piece he gives him his best pawn, namely, the king's bishop's pawn, which at the commencement of an even game is defended by the king only, so that this is the weakest part of the board, and it is still further weakened by taking away the pawn. The difference between pawn and move, and pawn and two moves, is considerable; the two moves enabling the first player to take up a very strong position, and greatly to cramp his opponent's game.

The following is one of the games won by the Automaton Chess Player, when it was exhibited in London in 1820. The chief merit of this machine consisted in the skill with which a living player was concealed within it. The player was M. Mouret, an accomplished master of his day, as was proved by the fact, that he gave the odds of the pawn and move to all comers, so that in setting up the men the reader will remove the K. B. P. from the Automaton's side of the board.

Consultation and Correspondence Games. There are not only many other kinds of openings and descriptions of odds which might be illustrated did space permit, but we might also give specimens of *consultation games*, in which a number of players divide themselves into two committees, each with a board and men in different parts of the room, and the best move is discussed before it is made; the pieces, however, are not allowed to be touched before the move is decided on. A first-rate player will sometimes play against a whole club in consultation. Consultation games have been played between the clubs of two distant towns, the moves being transmitted by means of the electric telegraph. Then there are *correspondence games*, in which the moves are sent through the post. In this case the pieces are allowed to be moved in order to decide on the best move. Games of this kind are long and tedious, and may last some years, as in the contest between the clubs of London and Paris, London and Edinburgh, &c.

Ends of Games.—It frequently happens that after playing some time there are only one or two pieces or pawns left on the board, and it is then a question whether either player have mating-power. Should one player be left with his K. and Q., against his adversary's K., he can win easily. Such is also the case with K. and R. against K., only the mate requires a larger number of moves. The K. and two Bs. against K. also win. The K. B. and Kt. against K. can win, but the mate is difficult. The K. and two Kts. against K. usually make a drawn game. The K. and two Rs. against K. and R. win, by forcing an exchange of rooks. K. and Q. against K. and R. usually win, but the weaker force can sometimes produce a stale-mate. K. and Q. against K. and two Kts., or two Bs., or Kt. and B., or R. and Kt., or R. and B. usually win. K., two Bs., and Kt. against K. and R., win. K. and R. against K. and B. usually make a draw. K. and R. against K. and Kt., also usually draw. K. and R. and B. against K. and R., is a doubtful case, but this, as well as some of the above, depend upon position.

Towards the end of the game the kings become useful pieces, and may act with great effect. The fate of a game often depends on being able to take what is called the *opposition*, that is, to place your king opposite to the adverse king, either on a file or a diagonal, so as to

Diagram 11.

BLACK.

WHITE.

have an odd number of squares between them: you thus gain the opposition or the *move*. This may be illustrated by a few examples.

In the annexed position (*Diagram 11*) your king is in opposition, and the object is to force the king to one of the sides of the board, when the mate is given by the rook.

- | | |
|------------------------|-------------------|
| 1. R. to K. R. 6 (ch.) | 1. K. to K. 2. |
| 2. K. to K. 5. | 2. K. to Q. 2. |
| 3. R. to K. Kt. 6. | 3. K. to Q. B. 2. |

If he had played back to his K. second, you would have checked at knight's seventh, and have forced him to the side of the board, but you now lose a move to see how he will play.

- | | |
|--------------------------------|--------------------|
| 4. K. to Q. 5. | 4. K. to Q. Kt. 2. |
| 5. K. to Q. B. 5. | 5. K. to Q. R. 2. |
| 6. K. to Q. Kt. 5. | 6. K. to Q. Kt. 2. |
| 7. R. to K. Kt. 7 (ch.) | 7. K. to Q. B. |
| 8. K. to Q. B. 6. | 8. K. to Q. |
| 9. R. to Q. R. 7. | 9. K. to K. |
| 10. K. to Q. 6. | 10. K. to K. B. |
| 11. K. to K. 6. | 11. K. to K. Kt. |
| 12. K. to K. B. 6. | 12. K. to K. R. |
| 13. K. to Kt. 6. | 13. K. to K. Kt. |
| 14. R. to Q. R. 8, Check-mate. | |

After this example it will be easily understood, that if the R. were exchanged for the Q., the mate would be more easy. The following

DIAGRAM 12.

BLACK.

WHITE.

position will serve to illustrate the nature of the mate with K. and two Bs. against K.

- | | |
|---------------------------|-----------------|
| 1. Q. B. to K. 3. | 1. K. to K. B. |
| 2. K. B. to K. Kt. 6. | 2. K. to Kt. 2. |
| 3. K. B. to K. R. 5. | 3. K. to K. B. |
| 4. Q. B. to K. R. 6 (ch.) | 4. K. to K. Kt. |
| 5. K. B. to K. Kt. 6. | 5. K. to K. R. |
| 6. K. to K. B. 6. | 6. K. to K. Kt. |
| 7. K. B. to Q. 3. | 7. K. to K. R. |
| 8. K. to K. Kt. 6. | 8. K. to K. Kt. |
| 9. K. B. to Q. B. 4 (ch.) | 9. K. to K. R. |
| 10. Q. B. checkmates. | |

The K. and two Kts. against K. cannot be forced; but if Black have a

Diagram 13.

BLACK.

WHITE.

pawn, the game may sometimes be won, since Black having a pawn

to move, is not stale-mated. The above (*Diagram 13*) is a case in point:—

- | | |
|--------------------------------|-------------------|
| 1. Kt. to Q. 4. | 1. P. to K. R. 7. |
| 2. Kt. to Q. B. 6 (ch.) | 2. K. to Q. R. |
| 3. Kt. to Q. Kt. 5. | 3. P. queens. |
| 4. Kt. to Q. B. 7, Check-mate. | |

These examples will suffice to illustrate the principle of mate, when there are only one or two pieces on the board. Some of the most refined and beautiful points of chess refer to pawn-play, which generally occupies an important chapter in every treatise on chess. It often

Diagram 14.

BLACK.

WHITE.

happens, that in cases of K. and P. against K., the K. can get immediately in front of P. before the P. reaches its sixth square. The game is then drawn. For example, in the position (*Diagram 14*):—

- | | |
|---------------------|--------------------|
| 1. K. to Q. B. 5. | 1. K. to Q. B. 2. |
| 2. P. to Q. 5. | 2. K. to Q. 2. |
| 3. P. to Q. 6. | 3. K. to Q. |
| 4. K. to Q. B. 6. | 4. K. to Q. B. |
| 5. P. to Q. 7 (ch.) | 5. K. to Q. |
| 6. K. to Q. 6. | 6. Is stale-mated. |

In some positions the winning of the game depends upon who has the move; but in certain cases, similar to the following (*Diagram 15*),

Diagram 15.

BLACK.

WHITE.

of two united pawns against two isolated pawns, White can win, whether he move first or not, for while the white K. can stop the advancing P., the black K. cannot play to Q. B. fifth, or capture the hindermost pawn, without the passed pawn moving on to queen. With the best play, however, this position is drawn.

- | | |
|--------------------|-------------------|
| 1. K. to K. 3. | 1. K. to K. 4. |
| 2. K. to K. B. 3. | 2. K. to K. B. 4. |
| 3. K. to K. Kt. 3. | 3. K. to K. 4. |
| 4. K. to K. Kt. 4. | 4. K. to K. B. 3. |
| 5. K. to Kt. 3. | 5. K. to K. 4. |
| 6. K. to B. 3. | 6. K. to B. 4. |

By this line of play the game is drawn.

Problems.—A department of chess which has called forth a large amount of ingenuity is the composition of problems, in which a certain position being given, one colour (generally white), is required to give

mate in a certain number of moves. Problems differ from *end games* in this, that whereas the latter are actual positions which have occurred, or might occur in play, the former may be built up or constructed, so as to carry out some idea of the composer. In certain cases, unusual conditions are attached to the solution, such as, that the mate is to be given with a particular pawn or piece, or on a particular square, or without touching certain pieces, or to check every move, or not to check until mate is given, or to compel your adversary to check-mate you, &c., &c. These absurd conditions are much better avoided, the best problems being made as natural as possible. Some composers make their problems in the shape of natural objects, such as an egg, a sword, a pyramid, a comet, &c., which is even more absurd than the conditions. We append three or four problems of great beauty and originality, together with their solutions.

No. 1. By CALVI.

BLACK.

WHITE.

WHITE MOVING FIRST, IS TO CHECKMATE IN TWO MOVES.

No. 2. By D'ORVILLE.

WHITE TO MOVE, AND MATE IN FOUR MOVES.

No. 4. THE CAPPED PAWN.

BLACK.

WHITE.

The above is an example of the *Pion Coiffé*, or "Capped Pawn," in which, at the commencement of the game, one of the players puts a paper cap or a ring over a particular pawn, and undertakes to check-mate his adversary with that pawn, without being allowed to queen it. In the above position, which is supposed to represent the end of such a game, White having to move is to give checkmate with the pawn in four moves.

The solution of a problem should not be discovered by setting up the position and moving the pieces about, but by the mental process of studying the diagram and so working it out.

CHESTNUT, or CHESNUT; ECONOMICAL USES. This tree is available for a great variety of uses in the arts and domestic economy. There are two kinds, the *Sweet Chestnut* and the *Horse Chestnut*.

The *Sweet Chestnut* is in most cases cultivated more for its fruit than for any other purpose. In England the chestnut is eaten in many ways—raw, roasted, stewed with cream, made into soup either with milk or gravy, stewed with salt-fish, or used as a stuffing for fowls and turkey. Evelyn speaks of the chestnut as being "a lusty and masculine food for rustics at all times, and of better nourishment for husbandmen than kale or rusty bacon; yea, or beans to boot." In the south of France and the north of Italy, chestnuts serve in a great measure as a substitute for bread and potatoes. The nuts laid by for winter vegetable are those which fall off the trees; while those which are beaten off are carried to Paris and other large towns for immediate use. As a means of depriving the nuts of their husks, they are trodden under foot by men wearing *sabots*, or wooden shoes. Chestnuts are dried in France, and preserved for many years; they are dried by the air, by the sun's heat, by a kiln, or by partial boiling, according to the mode in which they are to be used. The French make many dishes from chestnuts. *Galette* is a thick flat cake made with chestnut-meal, milk, salt, and sometimes a little butter and eggs, and baked on a hot stove or iron plate. *Polenta* is a thick porridge made by boiling the chestnut-meal in water or milk, and stirring it till it forms a thick paste, something like the oatmeal parrich of the Scotch. *Chatigna* is made by boiling the nuts whole, without their skins, in water with a little salt, till they become soft, and then mixing them up like mashed potatoes. *Marrow-glace* is made by dipping the nuts into clarified sugar, and then drying them. The nuts are also frequently cooked by boiling them in water containing the leaves of celery or sage.

The timber of the sweet or Spanish chestnut is much used for posts, fences, stakes, hoops, &c. The wood is more fitted for such purposes

than for beams or plants, as it is liable to become rent with fissures. It is used in France for making wine-casks; and for many purposes where most other woods would decay, chestnut timber is found very desirable.

The *Horse-Chestnut* has also its numerous uses. The fruit is eaten by animals: the meal is used in some places to whiten flaxen cloth; in others, to strengthen bookbinders' paste; and in France attempts have been made to produce sugar and spirit from it. The timber is used for flooring, cart-linings, sabots, packing-cases, and water-pipes; on being burned, it yields good charcoal and potash. The bark is used in tanning, in dyeing, and as a drug.

From 60,000 to 80,000 bushels of Spanish chestnuts (as the fruit of the sweet chestnut is called) are annually imported into this country, mostly for sale at Covent Garden Market.

CHESVAN or CHESHVAN, *חֶשְׁוֹן*, is the abbreviated name of the second month in the Jewish year, now usually employed instead of the proper term Marchesvan. The Jews believe, or pretend, that the full word implies "Bitter Chesvan," and that the epithet "bitter," *mar*, was added to the name, because no festival day occurs in the month! They leave it out in common parlance accordingly. [BUL; MARCHESVAN.]

CHEVAUX DE FRIZE, beams of wood or cylinders of iron, from six to nine feet in length, and pierced by iron rods or wooden pickets six feet long, which are pointed at each end and shod with iron; the pickets are placed six inches asunder, and pass through two opposite faces of the beam in directions alternately at right angles to each other, the cheval resting on the ground at the lower extremities of the pickets. A series of these, disposed in lines and connected together by chains, are placed in the ditch, on the berme, at the entrances or behind the glacis of a field fort; or on the breach made in the rampart of a fortress, in order to impede the enemy at the time of making an attack. The chevaux de frize made for the British service consist of hollow cylinders of iron in six feet lengths, sufficiently large in diameter to contain the iron rods or pickets when removed, for the purpose of packing for transport, from their positions in the holes made at right angles to one another in the cylinder, and into which they are fixed by keying or turning half round, after a projection on their surface has passed through a corresponding indent in the hole in the cylinder.

Chevaux de frize, on account of their portability and the facility with which they can be put together or taken to pieces, were much esteemed formerly, and were employed in the open field as a protection against charges of cavalry; but they are now seldom used for this purpose, being easily deranged by the enemy's artillery.

When Badajos was besieged in 1812, chevaux de frize, formed by sword-blades fixed in beams of wood, were planted by the defenders on the breaches in the Trinidad bastion and in the adjoining curtain, where they proved a fatal obstacle to the troops engaged in the memorable assault on that fortress.

CHEVY CHACE, the name of an old English ballad, founded upon the history of a hunting encounter which took place in 1388 at Atterburn, upon the south of the Cheviot Hills, between the martial families of Percy and Douglas. The older version of this ballad was first printed by Hearne, from a manuscript in the Ashmolean Museum at Oxford, and afterwards by Bishop Percy in the 'Reliques of Ancient English Poetry.' It begins,

"The Perse owt of Northumberlande."

According to a communication made by the Rev. J. J. Conybeare to the editors of the 'British Bibliographer,' there is now little doubt that the author of this ballad was one Richard Sheale, who dwelt at Tamworth, whom Percy and Ritson both agreed to consider as the transcriber only of the Ashmolean copy. The style of this ballad is rugged and uncouth, and it is written in the very coarsest and broadest northern dialect. There seems the best reason for believing that its composition may be dated about or soon after 1540.

The more modern ballad of Chevy Chace, that of which Addison has criticised the beauties in the 'Spectator' (Nos. 70, 74), begins,

"God prosper long our noble king."

Bishop Percy ascribes this version to the time of Queen Elizabeth, and it was probably late in her reign when it was written, or Sir Philip Sydney would have had no occasion to lament that the ballad of Chevy Chace, in his time, was so "evil-apparelled in the rugged garb of antiquity."

Bishop Percy has printed both ballads in his 'Reliques.'

CHIAROSCURO is a branch of painting, the object of which is to combine and arrange the light and dark parts of a picture to the best advantage. It has reference to the lights and shadows of the picture as a whole, however, and not to the mere natural lights and shadows of the several objects—in other words, it relates to what may be called the composition of light and shadow.

The term chiaroscuro is derived from two Italian words, *chiaro*, light, and *oscuro*, dark, and includes the treatment of bright and dark colours or tints, as well as simple light and shade. It is by chiaroscuro that relief and depth, and what is termed the *effect* of a picture, are produced; by a judicious contrast of bright colours with dark, or a combination of the two, or by their gradual blending; by involving one

part of the picture in shadow, while another part stands forth in full light; or by making the light gradually die away into the shadows. Leonarda da Vinci was the first who reduced the art of chiaroscuro to any thing like a system. It was afterwards practically improved by Correggio and by Titian, under whom it may be said to have attained perfection. It gives to Rubens his richness and brilliancy, to Rembrandt his magical luminousness. It must however always remain, from its nature, difficult to teach or subject to rules. To acquire excellence in the use of chiaroscuro, the student should study the properties of light, and the mode in which it is diffused, reflected, and separated into colours. He should refer to the works of the best masters, and observe the means which they have employed to imitate nature; and, above all, he should constantly watch and note down the effects of light and shade as exhibited in the objects around him under various modifications. The most powerful effects in painting will always be the nearest to nature; and the most pleasing will be those which are best selected out of the infinite variety which she presents for our choice.

CHICORY, in its botanical characteristics, is described under CICHORIUM, in NAT. HIST. DIV. Considered as a material for everyday use, it is a perennial plant, the whole of which is bitter and aromatic. The leaves, as well as the root, have been used in medicine, in the form of a decoction, as a tonic bitter, and as a diuretic. It is frequently used as a salad, especially when blanched. The luxuriant growth of the leaves of the chicory, and their speedy reproduction after they have been cut, suggested the more extensive cultivation of this plant as food for cattle and sheep; but, notwithstanding its abundant produce, it has not been found so much superior to other green food as to make its cultivation general.

Chicory has thence become an agricultural crop. It has a fusiform root like a carrot, from the crown of which large and succulent leaves spread out, with deeply-indented edges. M. Cretté de Panuel, who cultivated it near Paris, in a rich soil, produced extraordinary crops. The first year he cut it only twice, but afterwards four and five times in a year: it produced more green food than any other plant cultivated for this purpose. Arthur Young was so struck with it that he strongly recommended it to the notice of British agriculturists; and in the queries sent to various parts of the country by the Board of Agriculture, one was, whether chicory was cultivated in the district as green food for cattle. Some accurate experiments on a large scale were made in France at the national farm of Rambouillet, to ascertain the value of chicory compared with lucerne and other green food. The chicory was declared inferior, giving a disagreeable taste to milk and butter when cows are kept upon it. For sheep it is very good, and a small portion mixed with their other food may probably be a preservative against the rot.

To have the roots in perfection, the seed should be sown, or rather drilled, in April, like that of the carrot. If sown sooner, they are apt to run to seed. The land should be rich, deep, and light. The plants should be thinned out to six inches in the rows, and most carefully weeded. In September the leaves should be finally gathered and the roots taken up, which may be done with a common pitch-fork. The best preparation of the land for chicory is grass or clover. The manure should be laid on before it is ploughed up in autumn, which will accelerate the decomposition of the roots. The land should be ploughed very deep in spring, and laid light; the surface harrowed fine, and the chicory seed drilled in rows twelve inches apart, and rolled. Liquid manure spread over the ground will much accelerate the growth of the plants, which must be thinned out like turnips or carrots to six or eight inches from plant to plant.

Chicory is now chiefly cultivated in Belgium and Germany, for the purpose of preparing from the root a powder which can be substituted for coffee. The roots, when taken up in September, are cleaned by scraping and washing, split where they are thickest, and cut across in pieces about two or three inches long; these pieces are dried by means of a slow oven or a kiln. In this state it is sold to the merchants, packed in bags. It is afterwards cut or chopped into small pieces, and roasted exactly as coffee, ground in a mill, and packed in papers in pounds and half-pounds for retail sale.

Chicory was brought into use long before the once celebrated *roasted corn* of Henry Hunt. This latter was simply roasted rye; and, although used in large quantity, and sweetened with much sugar, it had but a flat and insipid taste. Chicory bears a much closer resemblance to coffee of middling quality. It was about the year 1808 that chicory became generally known in England, when Napoleon's anti-commercial policy led the nations of Europe to look around them for various substitutes for articles no longer obtainable with the same ease as before. The Germans and the French used chicory before the English; and the Germans still use it largely, often without any admixture with coffee. They even, as a question of economy, use the leaves of the plant in the same way.

There has been much said and written lately about the admixture of chicory with coffee. Many persons prefer coffee which has a little chicory added to it, as it is said that body, colour, and a soft pleasant aroma are imparted thereby. From one to two ounces to a pound of coffee is stated to be a proper proportion. It is however known that this proportion is enormously increased in the shops; for as chicory is much cheaper than coffee, fraudulent dealers do not fail to avail them-

selves of the circumstance. It is known that the very low-priced coffee of such vendors sometimes contains as much as two-thirds chicory to one-third pure coffee. If purchasers bought their coffee *whole*, and ground it at home, they might at once defeat this fraud. When coffee is over-chicoried, it acquires a mawkish taste, intermediate between those of treacle and liquorice; and its frequent use has a tendency to disarrange the digestive system.

The chicory trade has undergone some curious changes. The root was first imported in 1832, at the same duty as colonial coffee, with an imperative condition that the two should be sold separated, not mixed. In 1840, when the prices of tea and coffee were high, the Treasury issued an order, permitting chicory to be sold mixed with coffee, producing a compound that could be sold at a moderate price. Then arose a singular struggle: the coffee-merchants looked with suspicion on any encouragement given to chicory, as being likely to injure their trade; while the chicory-dealers insisted that fair play ought to be given to the commodity in which they dealt. Chicory was now grown in England, and was admitted into the market duty free; whereupon the coffee-merchants said, "Either tax chicory, or remove the tax from coffee." A few years afterwards, the consumption of chicory in England was variously estimated at from 18 to 28 millions of pounds annually. In 1852 a Treasury order appeared, forbidding the mixture of chicory with coffee in the same packet; but afterwards the conflict was thus settled: chicory may be sold mixed with coffee, but the fact of the admixture must be stated on a printed wrapper.

The extent to which coffee is adulterated by chicory is very great; the dishonest traders have a temptation to sophisticate, when coffee is from three to six times the price of chicory. But this is not all: chicory itself is adulterated. Samples of chicory purchased at retail shops have been chemically analysed, and have been found to contain carrot, parsnip, mangel-wurzel, beans, acorns, roasted corn, biscuit-powder, and burnt sugar; a few specially vile compounds were found to contain sawdust, red earth, burnt rags, and oakum or rope-yarn.

CHIEF JUSTICE. [COURTS.]

CHILBLAIN, a local but peculiar inflammation of the skin commonly appearing under one of three forms. The mildest form is attended with redness, swelling, and a sense of itching, often quite intolerable. In the second or severer form the colour of the swollen part is of a deeper red, sometimes of a dark blue colour, and at other times even of a purple hue. In the third or the severest form, small vesicles rise on the surface of the reddened and swollen skin, which are soon converted into sores, from which a thin irritating matter discharges, the irritating nature of which it is difficult to alter, or to bring the sores into a state of healthy suppuration.

That the inflammation of which this troublesome complaint is the consequence is of a peculiar kind, not very well understood, surgeons conclude because they find that it is not relieved by the applications which are most beneficial in ordinary inflammation.

The exciting cause of chilblain is always cold, and more especially cold applied after the part had been previously much heated. Hence those persons are most subject to the complaint who have contracted the bad habit of going immediately to the fire when they come home in winter with their fingers and toes very cold. Hence also the chief seats of the disease are those parts of the body which are most exposed to sudden alternations of heat and cold, as the nose, ears, lips, heels, and fingers. Young persons are more subject to it than adults, females than males, and it seems most frequently to attack persons of a fair skin.

The painful itching, which is perhaps the most troublesome part of this complaint, is best relieved by active and long-continued friction with camphorated spirits of wine, or with a mixture of two parts of camphorated spirits with one of Goulard's extract. Some surgeons speak highly of the efficacy of one part of the tincture of cantharides to six of the common soap liniment as a lotion. But "one of the best modes of curing chilblains of the milder kind is to rub them with snow or ice-cold water, or to bathe them in ice-water several times a day, keeping them immersed each time until the pain and itching abate. After the parts have been rubbed or bathed in this way, they should be well dried with a towel and covered with flannel or leather socks."

The stimulating applications, only in a more diluted form, appear also to be the best remedies when vesications arise. In this case the application of heat to the part affected should be most carefully avoided. When the vesicles terminate in sores, they require stimulating dressings.

But prevention is better than cure, and the most effectual mode of guarding against the annoyance of this irritating and often exceedingly protracted disease is to accustom the skin to moderate friction, to avoid clothing the parts too warmly, to avoid still more carefully sudden and great alternations of heat or cold; and accordingly to take particular care not to go immediately into a warm room or near a fire out of the cold air; and to wash the parts frequently with cold water. (Cooper's 'Surgical Dictionary'.)

CHILD KILLING. [INFANTICIDE.]

CHILD STEALING. [ABDUCTION.]

CHI'LIAD (from χιλιάς) is (or rather was) used to mean a thousand consecutive numbers. Thus from 1 to 1000 forms the first chiliad, from 1001 to 2000 the second, and so on.

CHILTERN HUNDREDS. A portion of the high land of Buck-

inghamshire is known by the name of the Chiltern hills. "Formerly these hills were a forest, consisting principally of beech trees, whence probably the name of the county, from *buch*, German; *bece*, Anglo-Saxon, the beech-tree. These forests afforded shelter to numerous banditti. To put these down, and to protect the inhabitants of the neighbouring parts from their depredations, an officer was appointed under the crown, called the steward of the Chiltern Hundreds." [BUCKINGHAMSHIRE, in GEOG. DIV.] The duties have long since ceased, but the nominal office is retained to serve a particular purpose. A member of the House of Commons, not in any way disqualified, cannot resign his seat. A member therefore who wishes to resign, accomplishes his object by accepting the stewardship of the Chiltern Hundreds, which being held to be a place of honour and profit under the crown vacates his seat. This nominal place is in the gift of the chancellor of the exchequer. Similar offices are the manors of East Hendred, Northstead, and Hempholme, and the escheatorship of Munster, which are used for the like purposes, and are resigned immediately.

CHIMES, a set of bells tuned to the modern musical scale, and struck by hammers acted on by a pinned cylinder or barrel, which revolves by means of clock-work. The term is also applied to the music, the tune, produced by mechanical means from the bells in a steeple, tower, or common clock.

Chimes differ from carillons (as the last word is commonly understood in England), inasmuch as the bells of the former are acted on by clock-work, those of the latter by keys struck by the hand. But the French apply the term *carillon* to the tune played, and, generally, to the series of bells, whether sounded by machinery or by hand; though the most accurate writers distinguish the latter kind as *le carillon à clavier*. The *carillons à clavier* comprise three octaves of bells, sounded by means of keys, similar to the pedals of an organ, which the performer strikes forcibly with hands clenched and sideways, the little fingers being guarded by a thick covering of leather. These keyed-carillons are found in many towns of Holland and the Netherlands. At Ghent they are remarkable; but the best specimen is at Amsterdam, where the *carillonneur* (M. Pothoff, formerly an organist in that city) used to display an extraordinary command of the instrument, on which he executed pieces in three parts—the base by means of pedals—with a rapidity rarely exceeded by judicious performers on the organ.

CHIMNEY (derived immediately from the French *cheminée*, which conveys the idea of a narrow passage, a diminutive or feminine form of *chemin*, but primarily from the Latin *caminus*), an enclosed passage funnel, or tunnel (see remarks on the etymology of TUNNEL), for the escape of smoke from a fire-place or furnace. The office of a chimney is not merely the removal of smoke, but also the production of draught to excite the combustion of the fire, by the heating and consequent rarefaction of the column of air inclosed in the funnel, the rising of which causes a partial vacuum, which should be filled with air admitted either through or over the burning fuel. [SMOKE; FURNACE; WARMING AND VENTILATION.]

The construction of house-chimneys is briefly treated of under HOUSE, but an explanatory diagram of a stack of chimneys is here introduced. But before so doing we shall enumerate, on the authority of Nicholson's 'Architectural Dictionary,' article "Chimney," the technical names given to the various parts of a chimney and fire-place. That which builders term the *fire-place* is the square recess or opening, facing the room, in which the stove is fixed or *set*. The *hearth* is the flat piece of stone, or marble, or metallic plate, immediately *under* the fire-place, while the large flat stone on the same level, but *before* the fire-place, though very commonly called the hearth, is technically called the *slab*. The vertical sides of the opening of the fire-place, and the projections from the face of the wall at each extremity of the slab, are the *jamb*s; and the horizontal head of the fire-place, the ends of which rest upon the jambs, is styled the *mantel*. *Covings* are the oblique facings of stone, marble, or metal, sometimes applied to the inside of the jambs to reduce the space at the back of the fire-place. *Funnel* is a general name applied to the cavity or passage of the chimney, from the fire-place to the top of the wall, the lower part of which, where the sides are sloped so as to contract the passage from the dimensions of the top of the fire-place to those of the flue, is called the *gathering of the wings*, or simply the *gathering*. The *flue* is the long narrow passage which extends from the gathering to the top of the wall, and which, whatever may be its course, should be of equal dimensions throughout its whole length; and the *throat* is the lower end of the flue at its junction with the gathering. The *breast* is that part of the wall which faces the apartment, and forms that side of the funnel which lies parallel to it; and the *back* is the opposite wall of the flue, parallel with the breast, but at the side farthest from the apartment. *Withs* are the narrow partition-walls which separate one flue from another rising beside it, and which form the sides of the flue, the *breast* and *back* being considered the front and back. A *stack*, or *chimney-stack*, is a wall containing a number of chimneys or flues arranged side by side. The *chimney-shaft* is the turret rising above the roof, to conduct a chimney or stack of chimneys to a sufficient height; and the *chimney-top* is the horizontal termination of the chimney-shaft, which is commonly surmounted by *chimney-pots*, to contract the upper end of the funnels or flues.

In modern English houses it is a common practice to form the

chimney-flues within the substance of the party-wall, an arrangement which, while it involves rather more brickwork than the older plan of forming them in the projecting jambs, has the advantage of leaving the width and projection of the jambs entirely dependent upon the taste of the architect. Where this plan is adopted in the case of two adjoining houses, the fire-places of which are back to back, the flues of two houses may be brought into one plane, as illustrated in the annexed diagrams, *figs. 1 and 2*. *Fig. 1* represents the arrangement of the flues in a four-story house, having two fire-places on each of the three lower

Fig. 1.

floors, and three on the upper floor, making nine in all. Being one of two houses with their flues united into one stack, the number of separate flues required is eighteen; but to show the arrangement more distinctly, the flues of one house only are tinted, while those of the adjoining house, rising from fire-places in the same positions but on the opposite side of the party-wall, are left in outline. The fire-places are indicated by a dark tint, and the positions of the floors and partitions are shown by dotted lines. *Fig. 2* represents transverse sections or ground-plans of the party-wall and flues, at the respective levels of the floors, *a*, *b*, and *c*, the flues of the one house being shown by a dark colour, while those of the other, left in outline in *fig. 1*, are shown white. If the stack were for a single house only, the arrangement of the tinted set of flues would need to be a little altered, so as to bring them close together in the chimney-shaft. Were the flues of the same house to be formed in the jambs, instead of being in the substance of the party-wall, the transverse section of the wall at the floor *a* would be

Fig. 2.

as in *fig. 3*, the inner jambs being widened to receive the flues from the basement story; but the arrangement of the flues in the upper

Fig. 3.

storeys would be altered, so as to distribute the flues as equally as possible on each side of the fire-places. It is however impossible in a lofty house, with flues of this description, to avoid the disfigurement of unequal jambs, since it will inevitably occur that in some cases a fire-place will have one flue in the one jamb and two in the other, or two flues on one side and three on the other. Another important advantage gained by placing the flues in the party-wall is, that the

projection of the jambs and breast may be reduced from 14 inches, the projection necessary when the flues are in the jambs, to 4½ inches. This advantage is not apparent in the cuts here given, because where fire-places are made back to back they cannot be made to recede so far into the wall as in other cases, it being necessary to preserve a thickness of nine inches between the backs of the two fire-places. The variations from the straight vertical course necessary to enable the flues which rise from the fire-places of the lower storeys to pass beside the fire-places of upper storeys, are useful in checking the tendency of the chimneys to smoke, and are frequently increased for that purpose beyond the degrees necessary for their arrangement in the stack; but in making them it is very desirable to avoid angles and sudden turns, which encourage the lodgment of soot, and impede the operation of the sweeping-machine. It is hardly needful to observe here the importance [SMOKE] of avoiding the communication of one flue with another. Such an arrangement is now very rarely permitted, excepting in the case of a copper or oven flue, which is frequently turned into a kitchen flue, instead of being carried up separately to the top of the stack.

Indispensable as chimneys now appear, they are of comparatively modern invention. Beckmann, who gives a long dissertation on their early history, with numerous references to passages in ancient writers bearing upon the subject ('History of Inventions,' English edition of 1814, vol. ii. pp. 62-101), says that the oldest certain account of chimneys with which he was acquainted occurs in the year 1347, when several chimneys at Venice were thrown down by an earthquake; but they were not in general use until long after that time.

On the subject of engine and factory chimneys the reader may consult Dr. Ure's 'Dictionary of Arts,' article 'Chimney,' where it is stated that the celebrated Montgolfier was the first to investigate the general principles of chimney-draughts, as applied in manufacturing establishments. Dr. Ure gives sectional and other diagrams of one of the immense and yet beautiful chimneys at the Camden Town station of the London and Birmingham (now London and North-Western) Railway, connected with the furnaces of the stationary engines for working the Euston inclined plane, subsequently removed. Hebert, 'Engineer's and Mechanic's Encyclopædia,' vol. i. p. 364, describes a curious mode of constructing chimneys with circular flues enclosed within common brick flues of an octagonal form, in such a manner that the inner flue, which forms the only passage for the smoke, is surrounded by a current of hot air supplied by enclosed chambers at the back of the fire-place, the effect of which is greatly to improve the draught. The internal flue is formed of a peculiar wedge-shaped kind of brick, which affords facilities for the formation of curves without any roughness or irregularity in the work, whenever it is desired to conduct the flue in a serpentine direction. This plan, which is patented by Mr. Hiort, is said to have been adopted in several public buildings with success. In the better sort of houses the flues are sometimes so constructed that they may be swept from openings in the basement story, without any communication with the rooms into which the fire-places open.

The celebrated chimney of the St. Rollox chemical works, near Glasgow, was not less than 450 feet in height, from foundations to top, its diameter at the ground line being 40 feet, and at the top 13 feet 6 inches. The chimney, subsequently destroyed, of Mr. Muspratt's soda ash manufactory, near Liverpool, was 406 feet high above the ground, 45 feet diameter at the base, and 9 feet diameter at the top; and the chimney of the Edinburgh gas-works is not less than 341 feet 6 inches high. In the 'Civil Engineer and Architect's Journal,' and in the 'Builder' (*passim*), many interesting statistics connected with this branch of construction are to be met with; whilst the theoretical principles it involves are to be found in Peclet's 'Traité de la Chaleur.'

CHIMNEY-PIECE, the assemblage of architectural dressings around the open recess constituting the fire-place in a room, and within which the fuel is burnt, either immediately upon the hearth itself, or in a raised grate or open stove. Accordingly, the fire-place being the spot around which persons naturally group themselves in an apartment, or near which they take their station—literally the focus of the domestic circle—the chimney-piece has always been made a principal object, and a chief point for decoration, so much so as to be considered almost essential to the character of a sitting-room; for though an equal degree of warmth and a more equable temperature may be obtained by means of flues for hot air, a room has a rather blank and comfortless appearance without a fire-place; and though its want may not be felt, the chimney-piece is missed as an architectural feature, there being about the same want of expression when it is absent as there is in a house which shows no chimneys. Both chimney-shafts and chimney-pieces were therefore properly made significant and ornamental features in our ancient domestic architecture. For a long time indeed, fire-places were used only for one or two principal rooms in a building, and were of very rude and primitive design, the funnel of the chimney projecting into the room, and sometimes sloping forward, downwards, and the opening for the fire-place being a simple arch, with scarcely any attempt at ornament. The more ancient examples are those of mere fire-places rather than chimney-pieces. In domestic architecture much was exceedingly uncouth and inconvenient, at the time when the Gothic style had attained in ecclesiastical edifices what has been considered by many its highest perfection. But as soon as

some degree of architectural refinement began to be introduced into the habitations of nobles, external dressings constituting a chimney-piece were added to the fire-place. The annexed example of one from Tattershall Castle, Lincolnshire, may serve as a type for such internal

feature where the Gothic style is employed, both on account of its fitness and propriety of character, and the happy union of simplicity with richness. It exhibits the style characteristically as employed for that particular purpose and no other, by those who were familiar with it, and who therefore did not, like some modern Gothic designers, look to tombs and gateways for ideas for chimney-pieces. Some other examples—one from the same building, and two from Windsor Castle—are given in Pugin's 'Gothic Specimens,' all of them very similar in their general character and proportions, in which respect and in regard to compactness and simplicity of composition they accord much more nearly with modern taste, and have a less 'Gothic' air than the cumbrous and extravagantly ornamented chimney-pieces in the Renaissance style of the Continent and our own Elizabethan. In these the design was carried quite up to the ceiling so as to form a sort of architectural frontispiece, composed of two or more stages piled up on each other, adorned with columns, pilasters, caryatides, termini, niches, &c., and presenting an overloaded mass of carving and sculpture. But though such compositions were generally exceedingly capricious, and equally fantastic and coarse in detail, some were real works of art—truly admirable for artistic beauty of design and masterly execution. In the palace of Fontainebleau were many sumptuous structures—for so they may be called—of the kind, and among those still remaining is the one in the ball-room, originally decorated with two bronze caryatides, larger than life, but for which columns are now substituted. Various magnificent examples, of the same period, occur in the Low Countries; two noted ones in the Hôtel de Ville at Courtrai, and one of matchless beauty for its exquisite carvings in chestnut-wood, in the Hôtel du Franc at Bruges. In our own country, chimney-pieces of the time of Elizabeth and James I. are by no means uncommon; many are remaining not only in mansions of that period which are still kept up, but in houses which have been almost completely modernised in all other respects. A great number and also a great variety of them may be found in Nash's 'Old English Mansions,' and Richardson's different publications illustrative of Elizabethan architecture. In general they are exceedingly heavy and cumbrous in their mass, 'over-informed' with ornament of all sorts, in the style of the ponderous cabinets of the time, and showing in fact sometimes like immense pieces of furniture of the kind, owing to their rather contrasting than according with the enrichment bestowed on other parts of the room. Some however are of comparatively sober design, and even those which are most extravagant as compositions, and over-loaded with ill-assorted details, are of interest as exhibiting numerous samples of ornament.

As the more regular Italian style gained ground, the fashion of chimney-pieces greatly changed; the decorated superstructure reaching from the chimney-piece itself to the ceiling was either discarded altogether, or greatly reduced so as to become no more than a carved framing to a panel. The chimney-piece and fire-place were reduced to nearly their modern proportions and dimensions, whereas the opening or fire-place had previously been of such size that a person might stand within it, as it resembled that of a large open kitchen fire-place; which, putting aside other objections, caused a room to appear low by comparison. At present the height of the opening is made nearly the same in all cases, namely, from three to three feet and a half, the width alone being increased accordingly as a larger fire-place than usual is required, and the dressings around it extended so as to proportion the chimney-piece in some degree to the size of the room as a piece of architectural furniture in it: thus like other furniture its dimensions are limited by purpose and convenience, for were such as they dictate exceeded, the chimney-piece itself would look gigantic, and the mantel-piece would be out of reach. When therefore a single fire-place of the usual size is insufficient, as for very spacious rooms or galleries, there are two or even more according to circumstances, and they must of

course be placed with strict regard to architectural symmetry: thus, if two, there is generally one at each end of the room, though both are sometimes placed on one side of it, namely, that facing the windows, equidistant from the centre, and if the room be an ante-room, with the door into it between them, and folding-doors at each end into the adjoining apartments. Again, if there are three chimney-pieces, one will be at each end, and the third in the centre of the side opposite the windows, though there are instances of even three being placed all on that side. More than that number are scarcely ever required,—even so many being rather for ornament and regularity of design than actual use. Apartments of such size as to require them on that account, are rarely used as ordinary sitting-rooms, and there is little occasion for fires in them at all when they are thronged with company. Still there is occasionally a greater number: the picture-gallery at Buckingham Palace, for instance, has no fewer than five chimney-pieces, namely, two on each side, and another at the north-end. Fire-places are sometimes made on the window side of the room, which although by no means to be recommended for general practice, or for more than one or two rooms at the most in the same house, has its advantages in particular cases. It is a convenient disposition for them in libraries, because a person can sit and read by the fireside and a window at the same time: it is also very agreeable to have a chimney-piece so placed when the windows command a fine prospect; thirdly, it produces a difference of character between that and the other rooms. In such case there must of course be a central pier for the fire-place, and that pier must be of such width as to allow the chimney-piece to be placed against it without seeming to be squeezed in between the windows. It is objected that when the chimney-piece is so placed, not only is the window side of the room apt to look crowded, but the opposite one to look blank; but that depends entirely upon circumstances: in a library, the opposite wall would be sufficiently filled with bookcases; or in any other room a sufficient balance may be kept up between the opposite sides by hanging some very large picture, or mirror, immediately facing the chimney-piece, or by a cabinet or some other large piece of furniture; or it may chance to be a very great convenience to have that side of the room free from a chimney-piece, as it affords the opportunity of obtaining spacious folding-doors in the centre of it into another apartment, or else a recess, either of which would sufficiently fill up that side of the room. Instead of being placed between windows, chimney-pieces are sometimes put beneath them, the mantel-piece forming the internal sill of the window, and the flue being carried up in one of the adjacent piers. Again, where fanciful effect is aimed at, a chimney-piece is set in an architectural compartment entirely filled with looking-glass, in which case the jambs and mantel-piece are made to project very considerably, so that, doubled by reflection, the chimney-piece has the appearance of being a solid and insulated mass of marble.

Marble is now the usual material for chimney-pieces even in ordinary houses, and such very general employment of it for the purpose has caused economy to be consulted by excessive plainness of design and scantiness of workmanship, sculpture being out of the question; the mouldings very few and plain, and the mantel-piece a mere shelf. Chimney-pieces of this class are manufactured by wholesale, and are kept like any other article of furniture ready-made, requiring only to be fixed when purchased. Convenient and economical as it may be, such a system is not calculated to advance taste, since a chimney-piece ought to be designed expressly for the particular room where it is to be put up. This is done of course in houses of a superior kind, and yet in some recent instances there is so far from being that accordance between the style of the chimney-pieces and the other architectural decorations of the room, that, although the former call for rather a greater than a lesser degree of embellishment, inasmuch as they are more closely observed, they have frequently very much less, consequently appear to be in a style of affected and harsh severity in comparison with all the rest. Worse than this, both style and keeping are sometimes so outrageously violated, that chimney-pieces of elaborate and frittered design, à la Louis Quatorze, are fixed in rooms whose other architectural dressings are marked by the opposite extreme of soberness or even plainness. Neither is that attention given to colour which ought to be: very dark or black marble is by no means the most suitable for such purpose, because instead of relieving the fire-place, the chimney-piece and fire-place together form a dull and sombre mass. This disagreeable effect is very greatly increased when—as is actually the case in the morning room of the Conservative Club-house—black marble chimney-pieces are introduced among scagliola columns and pilasters of pale or bright hues: all consistency of composition as to colour is destroyed, and instead of being ornamental objects, the chimney-pieces look no better than two dismal blotches in the architecture. In fact black is quite as unsuitable a colour for chimney-pieces as it would be for door-cases and window-dressings. Among collections of designs for chimney-pieces, Piranesi's 'Maniere di ornar gli Camini' is unrivalled for magnificence of ideas.

CHIMNEY-SWEEPER, a person whose trade it is to cleanse foul chimneys from soot. The actual sweepers were formerly boys of very tender age, who were taught to climb the flues, and who, from the cruelties often practised upon them by their masters, became from the commencement of this century objects of the particular care of the legislature. The first and chief Act by which regulations concerning them

were enforced was the 28th Geo. III., c. 48. It was followed by the 4 & 5 Will. IV., c. 35. This Act expired in 1842, when the 3 & 4 Vict. c. 85, intituled 'an Act for the regulation of Chimney-sweepers and Chimneys,' came into effect. By this Act, the compelling or allowing a person under twenty-one years of age to ascend or descend a chimney, or to enter a flue for the purpose of sweeping it, or of extinguishing fire, is prohibited under a penalty of not more than 10*l.*, or less than 5*l.* It is further provided by the same Act, that no child under sixteen years of age shall be apprenticed to a chimney-sweeper. This Act also contains regulations for the construction of chimneys. About the beginning of the present century, a number of public-spirited individuals joined in offering considerable premiums to any one who would invent a method of cleansing chimneys by mechanical means, so as to supersede the necessity of climbing-boys. Various inventions were in consequence produced. The principal parts of the one in general use are a brush and some hollow tubes which fasten into each other by means of brass sockets.

CHINA WARE. [PORCELAIN.]

CHINDEINE. [CINCHONA, ALKALOIDS OF.]

CHINESE ARCHITECTURE. The architecture of the Chinese may be considered unique in its style. Their buildings differ also in construction from those of Europe and the rest of Asia. The peculiar character of Chinese architecture is displayed in their royal palaces, temples, bridges, monumental arches, and also in their houses and sepulchres. The materials employed are wood, of which that most in use is the nan-mon, a kind of cedar, stone, marble, bricks, bamboo, and glazed or porcelain tiles. The construction of their dwelling-houses is directed by a public functionary, whom we may not inaptly designate a district surveyor. Every one is obliged to build his house according to his rank, and for every house a certain size and details are fixed. The ordinary habitations have only one floor. The houses called heon, that is of many floors, were once very much the fashion, and some were built above 200 feet high. Wooden columns, so placed

as to support the roof, are common, and are from eight to ten diameters in height. They are fixed on stone or marble bases, but have no capitals; an architrave of wood placed on the top of them runs through the wall of the house, and a beam which is carried through the upper part of the column, and passes through the wall also, is connected with the architrave on the outside of the house. The wooden pillars are always painted of a bright colour, commonly red, and varnished; the open work is usually green, and strong lines of blue, black, or gold relieve and give effect to the prevalent hues. The roofs are also covered, and the walls plastered with stained substances of brilliant colours. When fully painted, and decorated with their fanciful scroll-work and strange devices, the appearance of a Chinese house is singularly gay and brilliant. The roofs, which are slightly constructed of bamboo, are often double, and resemble one roof rising out of the other: they turn up at the eaves, at the angles of which are hung grotesque figures of dragons, &c. The framing of the roof, as will be seen by the cut, is quite different from the European method. Three or four transverse beams, placed one above another, serve as tie-beams, and by means of uprights the lower beam supports that above it, the lowest of all resting on the wooden columns already described. The construction is rude, but simple and effective; its character will be readily understood from the engraving. The columns and beams are often made of precious woods, and are inlaid with ivory, copper, and mother-of-pearl. Galleries or passages of intricate design abound, and are decorated in very pleasing taste with trellis-work and carving. Not the least singular appearance in a Chinese house is the door, which is often a complete circle; the window frames and sashes are formed of small pannels of various forms moulded out of clay, and neatly joined together. The sills of doors are of stone. The wood of the nan-mon is said by the Chinese to last more than a thousand years. Stone and marble, though in abundance, are more rarely used than wood, brick, and tile.

The palaces of the kings are built on large masses of alabaster as a

[Interior of Mansion.]

foundation. The palace of Pekin is on an immense scale, 2513 feet by 3235 feet. It is spoken of by the missionaries as presenting a very imposing appearance. The palace, which is divided into a number of courts, is composed of towers, galleries, porticoes, halls, and immense buildings: each court is more superb than the other as you approach towards the last court, the residence of the king, which is the richest of all.

The extraordinary respect paid by the Chinese to the dead has led them to the construction of rich and costly places of sepulture. Frequently the tomb is excavated out of the side of a hill, where a stone entrance structure in the shape of a horse-shoe, or rather a Greek Ω , is constructed, in a style that from its solidity and durability contrasts remarkably with the lightness and almost flimsiness of their dwelling-houses. These tombs are often constructed of granite, polished, and elaborately carved. But besides these there are tombs and monuments which exhibit a variety of architectural designs, often resembling the familiar forms of their buildings; even the double roof is carved on some mausoleums. The common people have only a cone of earth with trees on the summit, not unlike the barrows in Wiltshire. Several forms of tombs are given in Alexander's 'Costume of China.' The forms are round, square, hexagonal, and octagonal, and the form of the coffin is also imitated.

Another very remarkable kind of building is the *pae-low*, or honorary or monumental gateway (sometimes improperly called a triumphal arch), placed in the middle of streets, at the entrance of towns, and in front of temples, and even dwelling-houses of a superior grade. These

arches are erected sometimes at the command of the emperor, and at the public expense, to commemorate the merits of some public functionary; but in other cases they are raised by private persons of

[Chinese Tomb.]

distinction, to the memory of a relative. In general character they resemble the domestic edifices; thin pillars supporting a roof or summit of somewhat elaborate character. They always have a broad and lofty central passage, with a narrower and usually a lower one on each side. Sometimes they are constructed of wood, brightly coloured

and richly gilt; at others they are built wholly of marble, or of stone. An inscription placed on a kind of frieze under the projecting roof, records the name and titles of the deceased, and the cause of the erection of the memorial. These arches are erected to the honour of women as well as men. In the smaller towns they are built of wood, and the workmanship of many is very coarse. One of the finest and most substantial is that which serves as the entrance to the city of Amoy. At Ming-po the arches have as usual three gates, two small and one large, the larger one being in the centre. The door-posts are of stone. The entablature consists of three or four faces, and the architrave is morticed and tenoned, although it is of stone. Mouldings are seldom used in these faces, except in the highest or the highest but one; instead of a cornice there is a projecting roof which crowns the whole. The ornaments of some of these arches consist of men, birds, and flowers, and the ground is cut away so that the day-light is seen behind: the three openings are also arched.

The temples though not differing very greatly in architectural character from the costlier domestic buildings, form, from their number and costliness, a very important feature in the architecture of China. Their number is enormous. In Pekin, and in the environs, there are said to be 10,000 temples: those which are within the walls of the palace are richly finished, and some are magnificent. To a great extent the temples differ in their plan. That of Honang, opposite Canton on the south, is enclosed within an oblong court, 590 feet by 250, which in the interior is surrounded by cells for the priests or bonzes. You enter the temple by an open vestibule, the ascent to which is by a step, and in which are two colossal statues mounted on huge granite pedestals. This vestibule leads to another, in which are four colossal seated figures, formed of stucco. This last vestibule leads into another great court surrounded with colonnades and rooms behind them for the priests. The court contains three square temples, equidistant, and set upon a plinth along the centre of the court. These buildings are each 33 feet square, and rise to a height of two stories, the lowermost of which is surrounded by a peristyle of 24 columns. They have the usual roof-like summit. The first of these courts contains the figures of the sacred Buddhist triad; in the second is a single figure of Omīto Fō. The priests perform their religious ceremonies in these buildings. At the four corners of the court are other smaller and somewhat similar edifices but without columns, in which the chief priests reside. Under the colonnades and between the rooms of the ordinary priests, there are four chambers occupied by idols. Two smaller courts are placed on each side of the centre of the large court;

[Plan of Buddhist Monastery of Honang.]

these are surrounded by the kitchens, refectory, and hospitals; all the buildings are covered with green varnished tiles.

The annexed plan and more detailed description, from Davis's ARTS AND SCI. DIV. VOL. II.

'Chinese,' will, however, give a clearer view of this very remarkable structure, which may be taken as a type of its class.

a a is a handsome paved way, of considerable breadth, leading through the middle of the space occupied by the temple, and composed of large slabs of granite, well laid down; *b*, the *hill gate*, as it is called, though erected on a dead level, the Buddhist temples being generally in the recesses of mountains; *c, d*, two raised recesses, with various inscriptions in gilt letters on the walls; *e, e*, two colossal figures of gigantic divinities, guarding the entrance; *f, f*, the hall of the four celestial kings, each of them seated on a lofty pedestal, and as large as the two preceding figures: one of them is said to be the benefactor of the temple; *g*, the principal temple, in which are seen, fronting the entrance, three colossal gilded images of the Buddhist triad, called the "three precious Buddhas;" the round spot on the forehead of each marking their Indian origin. On each side of the entrance are seated gilded figures, on a much smaller scale, of the *eighteen Lohān*, or saints, who take care of the souls of those that die. A huge drum and bell serve, in this temple, to *awaken the attention* of the gods to their worshippers; *h*, a single image of Omīto Fō, or Amida Buddha; *i*, temple containing a very well executed monument of a vase-like shape and gigantic dimensions, carved in white alabaster, or gypsum, and sacred to the *relics* (called *Shay-ly*) of Buddha. The whole is surrounded by lanterns and lamps kept continually burning, and on the sides of the monument stand bowls of consecrated or holy water, said to be a specific for various disorders, particularly of the eyes; *j*, long, covered passages or cloisters, leading to the priests' apartments and offices; *k*, temple of *Kuān-yin*, a goddess worshipped chiefly by women; *l*, apartments of the chief priest or abbot of the monastery, where Lord Amherst's embassy was lodged in 1816; *m*, a great bell, struck morning and evening; *n*, apartments for receiving visitors, where may be seen an idol with many arms, evidently of Indian origin; *o, o*, two pavilions, containing images of Kuān-foo-tsze, and another warrior demigod, to whom the present dynasty attributes its success; *p*, a place devoted to the preservation of animals, principally pigs, presented by the votaries of the temple; *q*, a book-room and a printing-press, exclusively devoted to the sacred books of the Buddhist sect; *r*, a place for idols, near which are a number of miserable cells for the inferior priests; *s*, on this side there extends a considerable space of walled ground for the growth of kitchen herbs, and containing besides, a mausoleum, where are seen a number of jars, in which are deposited the ashes of the priests after their bodies have been burned. Here, too, is the building in which the act of cremation is performed. To the left of the temple are a variety of offices, as the kitchen, common room, &c., &c.

More characteristic than the temples are the pagodas, structures chiefly monumental in purpose, though often more or less closely connected with the temples. The term pagoda, which is a corruption of the Sanscrit *bhagavati*, "holy-house," is a name generally applied by Europeans to temples in the East, from China to Hindustan. The Chinese pagoda consists of several stories, usually nine, and generally comprises a porch, a vestibule or ante-sanctuary for the priests, and an inner sanctuary, containing the principal idol. Yet although called pagodas by Europeans, the name given by the Chinese themselves to such towers is *Taas*. They are very numerous throughout China. The most celebrated *Taa* is at Nankin. It is built of brick, but covered, both walls and roof, with plates of porcelain, and hence it is known as the Porcelain tower. Like most others, it is an octagon, with a diameter of about 42 feet, each face being 16 feet wide. It is upwards of 210 feet high, and is divided into nine stories, each of which has a marble gallery with gilt lattices, the stairs being formed within the thickness of the walls. From every story projects a kind of roof, at the angles of which bells are suspended. The summit is surmounted by a cupola, from which rises a lofty pole or mast about 30 feet high. When perfect, it is said to have had a very brilliant appearance, but it has long been in a ruinous condition. Of that at Tong-Tschang-Fou, the exterior is also of porcelain, but the walls themselves are of marble. Others have a single staircase in the centre carried up through all the different stories. Although so completely dissimilar in style, these *Taas* bear a strong analogy to the lofty detached pyramid tower-temples of the Hindoos. [HINDOO ARCHITECTURE.] Both seem to have originated in a common idea, differently modified, according to the taste and mode of building of the respective nations. On the whole, the Chinese pagoda must be admitted to be a very effective object, especially in a distant view of a city. The pagoda at Kew, built by Sir William Chambers, is a very poor representation of a Chinese pagoda, having neither the colours nor brilliant decorations of the Chinese.

Most towns have extensive walls high enough to hide the buildings, except the pagodas or towers, and wide enough to ride on horseback. The walls of Pekin, which are built of brick, are 42 feet 6 inches high, and they have small square towers at every 200 feet. In some places there are long inclined planes for the cavalry to ascend. The isolated castle of Tien-sing-foo, at the confluence of the Pei-ho and Eu-ho rivers, is of a square form and built of slate-coloured bricks; the walls are ramped or inclined inwards; the basement is of stone, and the entrance, which is arched with stones, is at some height from the ground, with a square window on each side. The top of the castle has battlements, and below them is a large torus-moulding on a level with

the terrace; just above the torus are small semicircular arches to let the rain run off the terrace. The parapets between the battlements are each pierced with two small holes, and a small guard-house with the

[Nine-storied Pagoda.]

roof having the usual turned-up eaves is built on the top of the terrace. The Great Wall of China is described under CHINA [GEOG. Div., vol. ii., cols. 467, 8]. Chinese bridges are noticed under BRIDGE.

CHININE. [CINCHONA, ALKALOIDS OF.]

CHINOIDINE. [CINCHONA, ALKALOIDS OF.]

CHINOLEINE. [CINCHONA, ALKALOIDS OF.]

CHINOVIC ACID. [QUINOVIC ACID.]

CHIOCOCCIC ACID. [QUINORATIC ACID.]

CHIRAYTA, the specific name, an imitation of the Sanskrit and Bengalee names, of a plant of the tribe of the Gentianeæ [AGATHOTES, in NAT. HIST. Div.], and so greatly resembling a Gentian, that it is referred to that genus by Dr. Wallich, who has figured it in his 'Plantæ Asiaticæ Rariores,' vol. iii. p. 33, t. 252. It has not yet been received into the London Pharmacopœia, but has found a place only in that of Edinburgh; that it merits, however, a more extended use is certain. It is probable that even in India two distinct plants, both gentianaceous, are designated by the name Chirayta; at least Dr. F. Hamilton Buchanan found in Nepaul two so termed. The smaller of the two is that which is here treated of. Continental pharmacologists have had sometimes the one, sometimes the other, supplied to them. Hence very erroneous accounts are met with of the habitudes and physical characters of the Chirayta. Geiger describes it as a perennial plant, native of Egypt as well as of India, and of larger dimensions than the plant now intended. The genuine Chirayta is an annual plant, about three feet high, flowering in the rainy season. The whole plant is taken up, and the proper time for collecting it is just when the flowers begin to wither. When dried it has an intensely but agreeable bitter taste, and is destitute of aroma. The root is possessed of the greatest bitterness. The bitter principle is readily imparted to water and to alcohol. As it is not easy to ascertain what plant the Continental chemists analysed, it seems best to follow the analysis of Mr. Battley, whose specimens must have been genuine, having been furnished by Dr. Wallich. According to this chemist, it contains a free acid, a bitter resinous extractive, with much gum, and chlorates, with sulphates, of potash and lime. No alkaloid has been detected in it; what is therefore sold as a sulphate of chiraytine is well known to be only the disulphate of quinia. In regard to the pharmaceutical preparations of chirayta, infusion and watery extract, or a tincture of it, are alone to be recommended. Not only is the decoction a most improper

form, but an infusion made with warm water is to be condemned, as this causes most distressing headache. Even to form the cold infusion a pint of water should not stand more than twenty minutes on half an ounce of the bruised plant. The tincture is a grateful addition to it.

Chirayta possesses the general properties of bitter tonics; but has at the same time some peculiar to itself, which fit it well for certain forms and complications of disease. Unlike most other tonics, it does not constipate the bowels, but tends to produce a regular action of the alimentary canal, even in those subject to habitual constipation. During its use, the bile becomes more abundant and healthy in character. The tendency to excess of acidity in the stomach, with disengagement of flatus, is much restrained by its use. These qualities fit it in a most peculiar degree for the kind of indigestion which occurs in gouty persons. It may, when necessary, be associated with alkaline preparations, or with acids; the latter are generally preferable. The same remark applies to its employment in the treatment of scrofula, in which alkalies are so freely and often injuriously employed. As a remedy against the languor and debility which affect many persons in summer and autumn, nothing is equal to the cold infusion of this plant. It may be taken twice or even more frequently daily, for a considerable time; then discontinued, and afterwards resumed. Children take it more readily than most other bitters. It is found to be a very efficacious remedy in India against intermittents, particularly when associated with the Guilandina Bonduc, or Caranga nuts. The debility which is apt to end in dropsy is often speedily removed by infusion of Chirayta; to which is added the tincture formed of it with orange-peel and cardamoms. Its efficacy in worm-cases has procured for it the name of *worm-seed* plant. The extract is given with great benefit in some forms of diarrhoea and dysentery, particularly if combined with ipecacuan, the emetic tendency of which it very markedly controls.

It is unnecessary to enter here into a review of the arguments adduced by Fee ('Cours d'Histoire Naturelle Pharm.' ii. p. 395) and Dr. Royle ('Flora of the Himalayas,' p. 277), to disprove the notion of Guibourt that this was the *Calamus verus* of the ancients. The calamus was more probably a grass, possibly that which in the present day is said to yield the *grass-oil* of Namur. Whencesoever obtained, this oil possesses great virtues. It is much used in India against rheumatism. It has the power in a most remarkable degree of preventing the hair of the head from falling off after acute diseases, such as fevers, or after confinements or prolonged nursing. It even restores it after it has fallen off. But it must be strong and pure; not the diluted feeble oil sold by perfumers under the name of oil of grass.

CHISLEU or CHISLEV, כִּסְלֵו, is the third month in the Jewish calendar; when earliest coinciding with our November, when latest with December. This is one of the two months which may have either twenty-nine or thirty days; a variation allowed in order to admit of the application of a law by which the beginnings of Tisri and Nisan were restricted to certain days of the week. The word is written *Χασελεῦ* in the Septuagint, and *Χασλεῦ*, or *Χασλεβ*, by Josephus; the Vulgate has Casleu, and the Samaritan reads Chaslim. All these readings concur to show that the ordinary vocalisation of the first syllable is erroneous. This month occurs in the Bible at the beginning of Nehemiah, and at Zachariah vii. 1. It is also found in the Apocrypha in 1 Maccabees iv. 52.

The several etymologies of the word from Hebrew roots are very unsatisfactory, and, however strange at first sight the suggestion of Benfey may seem, to derive Chisleu from the Persian Sheriur, a nearer examination will show much in its favour. The modern names do not appear till after the time of the Jewish subjection to the Persian empire, and one would expect to find them borrowed from the names used by the sovereign power; *Sheriur* must have been anciently something like *ksheriur*, from the Zend *kshatra vairya*, and with the ordinary variation of the liquids, *ksheriur* might be written in Hebrew characters, כְּסִלּוּ, as it is found engraved in one of the inscriptions at Palmyra, and read Caslul or Chislul.

The festival of the Dedication of the Temple by Judas Maccabæus is kept on the 25th day of Chisleu. See 1 Macc. iv. 52, and 2 Macc. x. 5. This festival is named חֲנֻכָּה, *khanukkah*.

CHIVALRY has commonly been represented as a great institution, invented in the 11th century, for a grand moral purpose—that of struggling against the deplorable condition of society at that period—of protecting the weak against the strong, and redressing individual injuries. So prevalent and so deeply rooted has been this notion of the origin of Chivalry, that we find it set forth even in the 'Histoire des Français' of M. de Sismondi, a writer usually so clear-sighted and so little a slave to the routine of his predecessors. But a closely attentive as well as philosophical analysis of the history of European society in the middle ages, proves this theory, or rather this supposition, to be deceitful. It shows us that Chivalry was not, in the 11th century, an innovation, an institution brought about by a special exigency which it was expressly adapted to meet. It arose much more simply, more naturally, and more silently; it was but the development of material facts long before existing—the spontaneous result of the Germanic manners and the feudal relations. It took its birth in the interior of the feudal mansions, without any set purpose beyond that of declaring,

first, the admission of the young man to the rank and occupation of the warrior; secondly, the tie which bound him to his feudal superior—his lord, who conferred upon him the arms of knighthood.

Of this we find an irrefragable proof in history of the term *miles* itself, which was constantly used in the latinity of the middle ages to designate the chevalier, or knight. Towards the end of the Roman empire, the verb *militare* signified simply to serve, to discharge some service towards a superior, whether the service itself were of a military or a civil nature. The service originally denoted by this expression, indeed, was, no doubt, the military service exclusively; but the use of the term had in course of time been extended until it embraced every subordinate office and function. After the Germanic invasions of the declining Roman empire, we find it frequently employed in speaking of the household of the barbarian kings, and the offices which their companions held about their persons. Soon, by a natural retrogression, in conformity with the new turn given to the social state, the term *miles* resumed its almost exclusively warlike character, and denoted the companion, faithful to the service of his superior. It thus became synonymous with *vassus*, or *vassallus*, and indicated that a certain man held of another a *beneficium*, or fee, and was attached to him by that consideration; in short, from the 9th to the 12th century, the word *miles* denoted, not the chevalier, or knight, as ordinarily conceived of, and as M. de Sismondi himself has described him, but simply the companion, the vassal, of a feudal superior.

Here we see the true and necessary origin of chivalry. But in the course of its development, when once the feudal society had acquired some degree of stability and self-confidence, the usages, the feelings, the circumstances of every kind, which attended the young man's admission among the vassal warriors, came under two influences which soon gave them a fresh direction, and impressed them with a novel character. Religion and imagination, poetry and the Church, laid hold on chivalry, and used it as a powerful means of attaining the object they had in view, of meeting the moral wants which it was their business to provide for. So early as the 9th century we find some religious ceremonies associated with the Germanic practices on these occasions. A succinct account of the reception of a chevalier, as practised in the 12th century, will show what progress this combination had made, and how powerfully the Church had laid its grasp on every particular of of that solemn act of the feudal life.

The young man, the squire, aspiring to knighthood, was first of all stripped of his garments and put into a bath, the symbol of purification. On his coming out of the bath, they clad him in a white tunic, the symbol of purity, a red robe, emblematic of the blood which he was to shed in the cause of the faith, and a black doublet, in token of the dissolution which awaited him as well as all mankind. Thus purified and clothed, the novice kept a rigorous fast for twenty-four hours. When evening came, he entered the church, and passed the night in prayer, sometimes alone, sometimes with a priest and with sponsors who prayed in company with him. The next morning, his first act was confession; after which the priest administered to him the communion; and after communion he heard a mass of the Holy Ghost, and commonly a sermon on the duties of a chevalier, and the new course of life on which he was about to enter. When the sermon was over, the novice advanced towards the altar, with the sword of knighthood suspended from his neck: the priest took it off, blessed it, and attached it to his neck again. The novice then went and knelt before the lord who was to knight him. "To what end," the lord then asked him, "do you desire to enter into this order? If it is that you may be rich, repose yourself, and be honoured without doing honour to knighthood, then you are unworthy of it, and would be to knighthood you should receive, what the simoniacal clergyman is to the prelacy." And on the young man's answering that he promised well to discharge the duties of a knight, the lord granted his request.

Then did knights in attendance, and sometimes ladies, approach the novice, and array him in his novel garb, putting on first the spurs, next the hauberk or coat of mail, then the cuirass or breast-plate, then the brassards or arm-pieces, and the gauntlets, and lastly girding on the sword. Then he was *dubbed*, to use the modern English expression, derived from the French *adoubé*, which, according to Ducange, signified *adopted*. The lord rose from his seat, went up to him, and gave him the *accolade*, that is, three strokes with the flat of his sword upon the shoulder or the nape of the neck, and sometimes a blow with the palm of his hand upon the cheek, saying, "In the name of God, Saint Michael, and Saint George, I make thee a knight;" and sometimes adding, "Be thou brave, bold, and loyal." The young man being thus knighted, they handed him his helmet, and brought him a horse upon which he sprang, usually without the aid of the stirrup, and caracoled within the church, brandishing his lance and flourishing his sword. Then quitting the church, he went and exhibited himself in like manner in public, beneath the castle walls, before the populace, whom he found eagerly awaiting their share of the spectacle.

It is easy to recognise in all this the influence of the priesthood, studious to associate religion with every circumstance of a solemnity so important in the warrior's life. Not only have the Christian sacraments their place in the ceremonial, but several of the observances more peculiarly chivalric, are assimilated as much as possible to the administration of a sacrament. Such was the share taken by the ecclesiastical order in what may be called the exterior material part of

the reception of a knight. And when we look into the moral character of chivalry, when we examine the series of oaths required of the knights at various periods from the 11th to the 14th century, and mark the ideas and the feelings with which it was sought to imbue them, we find the clerical influence no less distinctly apparent; and, indeed, a part of the oath was, that the knight should defend the rights of holy church, and respect religious persons and institutions. Certain it is, that in the obligations thus imposed upon the chevalier, we find a moral development extremely foreign to the state of lay society at that period. Moral notions so exalted—often so delicately scrupulous—above all, so humane, and so constantly impressed with the religious character, evidently emanated from the clergy. They alone then viewed the duties and relations of men in such a light; and their influence, it must be owned, was constantly employed in directing towards the fulfilment of those duties, and the improvement of those relations, the ideas and the usages to which chivalry had given birth. Whatever evils resulted from the unscrupulous and improvident use which the Roman Church made of this direct influence over the power of the sword, in promoting so many crusades against the infidel and the schismatic, it undeniably made use of the chivalric institutions which feudalism had brought forth, in labouring to introduce internal peace in society, and a stricter and more comprehensive morality into individual conduct.

In proportion as this endeavour succeeded, and as chivalry more and more appeared under a character at once warlike, religious and moral, at once conformable and superior to the actual manners, it seized upon and inflamed the imaginations of men; and in like manner as it had intimately bound itself up with their belief, so also it became the ideal standard of their aspirations, and the source of their most exalted pleasures. Poetry, in short, laid hold on chivalry as religion had already done. As early as the 11th century, the chivalric ceremonies, duties, and adventures, formed the mine to which the poets resorted for the means of charming the people, of at once gratifying and stimulating that craving of the imagination, that thirst for incidents more varied and more stirring, for emotions purer and more elevated, than real life affords. For it should be observed, that in the earlier stages of society poetry is not merely a national pastime; it is also a means of progress, exalting and developing man's moral nature. The poetical remains that have descended to us from that age show, that the poet imposed upon the chevalier the fulfilment of the same duties, and the practice of the same virtues, as were inculcated in the more solemn exhortations of the priest.

It is an oft-repeated observation, that all this was mere poetry, a fine chimæra, bearing no resemblance whatever to the reality. And indeed, when we consider the state of manners in those three centuries, and the incidents of daily occurrence that filled the lives of men, the contrast between the duties and the actions of the chevaliers is truly shocking. The period before us is undoubtedly one of the most grossly brutal in the history of European society, one in which we find the greatest amount of crime and violence, in which the public peace was most incessantly disturbed, in which the most dissolute manners prevailed. To any one attending only to the positive and practical state of society, all this poetry and morality of chivalry looks like sheer falsehood. Yet it is undeniable that the chivalric morality and poetry existed simultaneously with these disorders, with this barbarism, with all this deplorable social state. The monuments are before us: the contrast, we repeat, is shocking, but it is real.

This very contrast, however, forms the great distinctive characteristic of the middle ages. When we look into other social systems, as the Greek and Roman, when we examine, for instance, the early stage of Greek society, its heroic age, of which the poems that bear the name of Homer present a faithful mirror, we there find nothing resembling the contradiction that strikes us in the middle ages. The practice and the theory of manners are there nearly accordant. We do not find men having ideas much purer, nobler, and more generous than their daily acts. Homer's heroes seem quite unconscious of their own brutality, ferocity, selfishness, and covetousness; their moral science is no better than their conduct; their principles are on a level with their acts. We find it to have been the same with all other social systems in their vigorous and turbulent youth. But in Europe, on the contrary, in the middle ages, while the deeds are habitually detestable, while crimes and disorders of every description abound, yet we find dwelling in the minds and imaginations of men nobler instincts and more exalted aspirations. Their notions of virtue are much more developed; their ideas of justice incomparably better than what is practised around them, than what they practise themselves. A brighter ideal of morality hovers, as it were, above that rude and stormy social state, attracting the view and commanding the respect of men whose lives are little conformable to it. Christianity must undoubtedly be ranked among the principal causes of this fact; for its great characteristic is, its labouring to inspire men with a high moral ambition, to keep constantly before their eyes a standard infinitely superior to human reality, and stimulate them to attain it. But whatever be the cause, the fact is indubitable. We find it everywhere in the middle ages, in the popular poetry as well as in the exhortations of the priests. The moral conceptions of men rose far above the practice of their lives. Nor let it be thought, because those conceptions did not govern their actions, because their practice so strangely belied their

theory, that the influence of the theory was absolutely null. The habitual judgment of men upon human actions is not without its effect. It has been justly remarked, that a bad action is better than a bad principle: a bad action may remain isolated and solitary; but a bad principle is constantly fructifying; for after all, it is the mind that governs; and a man acts from reflection much oftener than he is himself aware of. In the age of chivalry, we repeat, the principles were infinitely better than the acts. For instance, at no period perhaps has the intercourse between the sexes been more licentious; yet never was purity of manners more strongly enjoined or more feelingly described; and perhaps the fantastic elevation given to the female sex by the laws of chivalry, may have tended ultimately to place woman in her true position as the equal companion of man. Nor was purity of manners a theme for poetic eulogy alone. We find from a multitude of testimonies that the public thought in this particular as the poet spoke, that the prevailing moral notions were pure and noble amidst all the rudeness and licentiousness of conduct.

This, then, was the grand moral characteristic of chivalry, which entitles it to an important place in the history of modern civilisation. If, on the other hand, we regard it not in a moral but in a social point of view, not as an idea but as an institution, it merits but slight consideration; for though it had a great and stirring part in the world's affairs, yet, as already shown, it did not constitute an actual specific institution at all. The feudal lords, the possessors of fiefs, were alone chevaliers; they alone, with few exceptions, had the right to become so. The knights formed no separate class of society with distinct functions and duties. Thus chivalry, properly so called, being inseparably bound up with feudality, could not survive its extinction; and accordingly, so early as the 14th century, when compared with its condition in the 12th, we find it rapidly declining.

It had, however, given birth to the religious orders, as the Templars, the knights of St. John, and the Teutonic knights; and it was beginning to produce the courtly orders—those of garters and ribbons—the knighthood of mere rank and parade. It was destined to tincture yet a long while the manners, the language, and the literature of European society. But the true chivalry, that to which alone the name can strictly be applied, flourished and fell with feudalism.

CHLOCARBETHAMIDE. *Chloracetamide. Trichloracetamide* ($\text{NH}_2\text{C}_2\text{Cl}_3\text{O}_2$). One of the chlorinated derivatives of acetamide. [AMIDES.]

CHLONAPHTASE ($\text{C}_{20}\text{H}_7\text{Cl}$). One of the numerous series of substitution products obtained by Laurent from naphthalene (C_{20}H_8). For further details respecting these bodies, see Miller's 'Elements of Chemistry,' vol. iii. p. 577.

CHLOR—CHLORO. Prefixes applied to designate a very large number of substances, chiefly organic, containing chlorine. The great majority of these bodies constitute what are termed *substitution* products, which are produced by the substitution of a certain number of atoms of chlorine for the same number of atoms of hydrogen in an organic body. Thus chloracetic acid ($\text{C}_2\text{H}_3\text{ClO}_2$, HO) is acetic acid in which one atom of hydrogen has been replaced by one of chlorine. Some of these substitution products are described under their respective names, the rest, if of any importance, are mentioned under the name of the substance from which the derived name has been formed, by the addition of one of the above prefixes. Thus *Chloraniline* will be found under **ANILINE**. *Chlorobenzoic Acid* under **BENZOIC ACID**, &c.

CHLORACETAMIC ACID, *Quadrchloracetamide* [$\text{NHCl}(\text{C}_2\text{Cl}_3\text{O}_2)$], one of the chlorine substitution products derived from *acetamide*.

CHLORACETAMIDE. [CHLOCARBETHAMIDE.]

CHLORACETHYPHIDE, another name for *phosphide of trichloracetyl*, or, as it might be more appropriately called, *trichloracetphosphamide*. $\left(\text{P} \begin{array}{c} \text{C}_2\text{Cl}_3\text{O}_2 \\ \text{H} \\ \text{H} \end{array} \right)$. [AMIDES.]

CHLORACETIC ACID ($\text{C}_2\text{H}_3\text{ClO}_2$, HO), a substitution acid obtained by exposing acetic acid diluted with half an atom of water to dry chlorine, in the shade. If the action takes place in sun-light, *trichloracetic acid* is produced. Chloracetic acid closely resembles acetic acid in its appearance and properties, and it is only of interest as showing that the hydrogen of negative organic bodies may be replaced by chlorine with scarcely any sensible alteration in properties.

CHLORAL, *Trichloraldehyde, Trichlorinated hydride of Othyl* ($\text{C}_2\text{Cl}_3\text{O}_2\text{H}$), a liquid prepared by Liebig with chlorine and alcohol, from the first syllables of which words its name is derived. To form it, a current of dry chlorine gas is passed into anhydrous alcohol, at first kept cool, but afterwards sufficiently heated to expel the hydrochloric acid formed. During the action of these substances one portion of the chlorine unites with the hydrogen of the alcohol to form hydrochloric acid, and another portion with its oxygen and carbon to constitute chloral. When the operation has been long continued, a liquid of the consistence of a syrup is procured, which afterwards becomes solid; it is a hydrate of chloral containing some undecomposed alcohol and a portion of hydrochloric acid. It is then to be shaken with concentrated sulphuric acid, which combines with the water, and the chloral rises in a fluid state to the surface; this is to be mixed with lime, and by distillation the chloral is obtained free from hydrochloric acid.

Chloral is a colourless transparent oily-looking fluid; its smell is pungent, and its taste but slight; its specific gravity is 1.502; at about 200° Fahr. it boils, and the vapour condenses unchanged. Water when

warmed dissolves chloral, but when mixed with a small quantity of it, they combine, when agitated, into a solid crystalline hydrate. By alcoholic solution of potash or soda it is decomposed, formate of potash and chloroform being produced. [OTHYL, HYDRIDE OF].

CHLORALBIN ($\text{C}_{12}\text{H}_6\text{Cl}_2$). A chlorinated derivative of carbolic acid.

CHLORALIDE ($\text{C}_{12}\text{H}_6\text{Cl}_7\text{O}_8$?). An unimportant product of the decomposition of **CHLORAL**.

CHLORALÖIL ($\text{C}_{13}\text{ClO}_5$?). A product of the action of chlorine upon the juice of the aloe.

CHLORAMILAL ($\text{C}_{10}\text{H}_8\text{Cl}_3\text{O}_3$?). A liquid product of the action of chlorine upon amylic alcohol. It appears to stand in the same relation to amylic alcohol as chloral does to vinic alcohol. [CHLORAL.]

CHLORANIL. [QUINONE, PERCHLORINATED QUINONE.]

CHLORANILAM. [QUINONIC ACID.]

CHLORANILAMIC ACID. [QUINONIC ACID.]

CHLORANILAMIDE. [QUINONIC ACID.]

CHLORANILAMMON. [QUINONIC ACID.]

CHLORATES. [CHLORINE; CHLORIC ACID.]

CHLORAZOL ($\text{C}_8\text{H}_8\text{Cl}_3\text{N}_2\text{O}_8$?), a very poisonous acid liquid, obtained by the action of nitrohydrochloric acid upon albumen. It possesses a very penetrating odour, is insoluble in water, but soluble in alcohol, and has a specific gravity of 1.555.

CHLORAZOSUCCIC ACID. [SUCCINIC ACID.]

CHLORELAYL-HYPOSULPHURIC ACID. [CHLOROMETHYL-SULPHUROUS ACID.]

CHLORETHERAL. [ETHER.]

CHLOREXTHOSE, *Oxide of perchlorobrominated ethyl* ($\text{C}_2\text{Cl}_6\text{Br}_2\text{O}_2$) [ETHER.]

CHLORHYDRIC ACID. [CHLORINE; HYDROCHLORIC ACID.]

CHLORHYDRIN, or *Hydrochlorate of Glycerin*, less water. According to M. Berthelot, three chlorhydrins exist:—

Monochlorhydrin is obtained by saturating glycerin with hydrochloric acid gas and maintaining the mixture at the temperature of boiling water for thirty-six hours. Saturation with carbonate of potash, agitation with ether, and evaporation of the ethereal solution, will yield a product that by distillation at a temperature of 440° Fahr. furnishes nearly pure monochlorhydrin. It may be quite purified by treating with lime and ether.

This substance is a neutral oil, of a cooling ethereal odour and a sweetish taste, becoming after a time pungent. It is miscible with water and ether. It burns with a white flame bordered with green, and gives off hydrochloric acid. It is slowly and with difficulty saponified by oxide of lead, glycerin being set free. It remains fluid at 35° below the zero of Fahrenheit's thermometer.

Dichlorhydrin is prepared by dissolving glycerin in twelve or fourteen times its weight of fuming hydrochloric acid, and subjecting the mixture to a temperature of 212° Fahr. for eight hours. It is purified in the same way as monochlorhydrin.

Dichlorhydrin is also a neutral oil, of decided ethereal odour. Its density is 1.37. Boiling point, 352° Fahr. In other respects it much resembles monochlorhydrin.

Epichlorhydrin is formed when dichlorhydrin is exposed for many hours in hermetically sealed vessels, filled with hydrochloric gas, to a temperature of 212° Fahr., or when dichlorhydrin is heated for some time with large excess of fuming hydrochloric acid. It is purified in the same manner as the other chlorhydrins. Its odour resembles chloride of ethyl, but is more persistent. Its specific gravity is between 1.2 and 1.3. Boiling point, between 248° Fahr. and 266° Fahr. Its chemical composition is indicated above.

CHLORHYDROPHENIDE. [PHENYL, CHLORIDE OF.]

CHLORHYDROPROTEIC ACID. The precipitate produced by hydrochloric acid in a solution of albumen is regarded by Mulder as a peculiar acid to which he has given this name. It contains 3.7 per cent. of hydrochloric acid.

CHLORIC ACID. [CHLORINE.]

CHLORIDES. Compounds of chlorine with other elements. The compounds with non-metallic bodies will be found under **CHLORINE**, and those with metals under the names of the respective metals; thus chloride of manganese will be found under **MANGANESE**, &c.

CHLORIMETRY (*Chlorometry*). The measuring of the amount of chlorine available for bleaching or disinfecting purposes in any compound in which it is contained.

The estimation of the commercial value of a sample of bleaching powder (chloride of lime) [**CALCIUM, Chlorine and**], is most conveniently performed by the process known as *Dalton's test*. This operation is based on three chemical facts: first, protoxide of iron is converted into peroxide of iron by the action of free or loosely combined chlorine; second, the amount of chlorine necessary to effect this action on a given weight of protoxide of iron is always the same; third, red prussiate of potash (ferricyanide of potassium) gives with protosalts of iron a blue precipitate, with persalts of iron no precipitate; this last enables the experimenter to ascertain when the action is complete.

It follows, therefore, that as we know what amount of chlorine is

necessary to convert a given weight of protosalt of iron into persalt of iron, it is only necessary to add our solution of bleaching powder of unknown strength to that given weight of protosalt of iron, till it ceases to yield a blue precipitate with red prussiate of potash, when the amount of chlorine in the quantity of bleaching solution we have used is at once indicated; and if we have made that solution with a weighed quantity of bleaching-powder, the strength, and therefore the commercial value of that powder is, by a very simple calculation, readily ascertained. The following are the details of this process:—

78.1 grains of pure, dry, recently-prepared protosulphate of iron (green vitriol) are dissolved in about two ounces of water, and a little sulphuric or hydrochloric acid added; to convert this into persulphate of iron, ten grains of chlorine are necessary. Fifty grains of the sample of bleaching-powder are rubbed in a mortar with a little water, and the mixture introduced into such a burette as under the article ALKALIMETRY is designated an alkalimeter; the mortar is washed with a little more water, and the liquid added to that already in the burette, which is then filled up to 0, and the orifices being closed by the finger and thumb, thorough mixture is promoted by agitation; each division marked on the burette will now contain half a grain of bleaching-powder. To the solution of protosulphate of iron, placed for convenience, and to ensure accuracy, in a stoppered bottle of about six ounces capacity, is added the bleaching solution from the burette, till, after agitation, a drop placed on a white plate gives no blue precipitate, but only a slight green colouration, when a drop of solution of red prussiate of potash is added to it. The number of burette divisions of bleaching solution used will obviously contain ten grains of chlorine; and, as each division contains half a grain of bleaching-powder, the whole number used in the experiment, divided by two, indicates the number of grains of chloride of lime that contain ten grains of chlorine. A short calculation gives the amount of available chlorine in 100 grains of the sample of chloride of lime subjected to analysis. Let m represent the number of measures used, then

$$\frac{m}{2} : 10 :: 100 : x$$

x will be the percentage of available chlorine.

The reaction that takes place will at once be seen by a glance at the following equation:—

Two other chlorimetrical processes have been proposed, both similar in principle, but not generally superior, to the one just described. In one, arsenious acid (AsO_3) is used in the place of the protosulphate of iron; the chlorine converts it into arsenic acid (AsO_5). In the other, yellow prussiate of potash (ferrocyanide of potassium) is the agent employed to absorb the chlorine; from every two equivalents of it ($2\text{K}_2\text{Cfy} = \text{K}_4\text{Cfy}_2$), one equivalent of chlorine abstracts one equivalent of potassium, forming chloride of potassium, leaving an equivalent of the red prussiate of potash (ferrocyanide of potassium = K_3Cfy_2). The arsenious acid process is known to be complete when a few drops of indigo solution, with which the mixture is tinted, are decolorised; the prussiate process is known to be complete when the mixture no longer gives a blue precipitate with a persalt of iron.

Chlorimetry is almost an hourly operation with the calico bleachers, inasmuch as the dilute solution of chloride of lime contained in their steeping vessels is, of course, much weakened by the immersion of a large quantity of unbleached goods; and the strength of the weakened solution requires to be known, in order that the proper quantity of the strong stock solution of chloride of lime may be added to restore the bath to its original strength. This is the more important on account of the limited range of strength of the steeping liquor, within which the cotton is properly bleached: if too strong, the goods are injured; if too weak, the fabric still remains brown. It is, therefore, very necessary that the calico-bleachers should possess a chlorimetric process that can be quickly, as well as accurately performed; and for this reason they usually adopt the method known as—

Crum's process. This test is based on the same principles as Dalton's test, namely, that chlorine converts a protosalt of iron into a persalt, and that a given quantity of the protosalt always requires the same amount of chlorine for its conversion; but the colour of a constant volume of the bleaching solution containing excess of protosalt of iron is made use of to determine the amount of persalt of iron in it; the intensity of this colour is obviously in direct proportion to the quantity of available chlorine in the volume of bleaching solution used. The following are the details of this operation:—

The protosalt of iron used is the protochloride, and is made by digesting excess of cast-iron turnings in hydrochloric acid, diluted with about half its bulk of water, at the temperature of boiling water, till all action has ceased. When cold, this solution is diluted till it has a specific gravity of 1.200, equal to 40 degrees on the scale of Twaddell's hydrometer, the instrument usually adopted by manufacturers for taking specific gravities. This liquid, mixed with acetic acid of sp. gr. 1.048, forms the proof solution. Diluted with water, it is colourless,

but the addition of chlorine gives rise to the formation of peracetate of iron, which has a peculiarly intense red colour. A quantity of this proof solution, measuring about a quarter of an ounce, is put into a clear white glass moulded phial of two ounces capacity, which is then filled up with a solution of chloride of lime that has a specific gravity indicated by one-twelfth of a degree on Twaddell's hydrometric scale. This operation is repeated with eleven other phials of exactly equal diameter, the bleaching solution with which they are filled up being each time carefully made one-twelfth of a degree stronger, so that the last phial will be filled up with bleaching-solution of one degree in strength (= sp. gr. 1.005). They should all be well corked and placed side by side in a frame, leaving a little space between every other one.

The steeping solution used by calico-bleachers usually ranges from one-half to one degree Twaddell, and when weakened by the immersion of a parcel of goods, its strength is at once ascertained by filling up with it a phial containing proof solution similar to those just described, and placing it by the side of the standard phial nearest to it in colour; the strength of the solution in that phial being known, the strength of the bleaching-liquid tested is at once indicated. If now the quantity of steeping solution used in one operation is known, and if a concentrated solution of chloride of lime is kept in stock, made always of the same strength, a table may be constructed which shall show at a glance the amount of stock solution required to be added to the weakened steeping-liquor, to make it stand at the desired strength. These conditions always exist in bleaching-works. The steeping vessels described in Mr. Crum's paper required 1440 gallons of liquid to fill them up to a mark indicating the proper height for receiving goods, a quantity more conveniently expressed by 288 measures—a measure containing five gallons, the quantity most easily carried at a time. The stock solution of bleaching-powder was always made of a density indicated by six degrees on the scale of Twaddell's hydrometer. The following table was then constructed:—

To stand $\frac{8}{12}^\circ$.		To stand $\frac{6}{12}^\circ$.	
0 requires 32 measures.		0 requires 24 measures.	
1 " 28 "		1 " 20 "	
2 " 24 "		2 " 16 "	
3 " 20 "		3 " 12 "	
4 " 16 "		4 " 8 "	
5 " 12 "		5 " 4 "	
6 " 8 "			
7 " 4 "			
To stand $\frac{4}{12}^\circ$.		To stand $\frac{3}{12}^\circ$.	
0 requires 16 measures.		0 requires 12 measures.	
1 " 12 "		1 " 8 "	
2 " 8 "		2 " 4 "	
3 " 4 "			

This table shows, for example, that if the steeping liquor is required to be of a strength indicated by $\frac{8}{12}$ of a degree Twaddell, the 288 measures must contain 32 measures of the stock-bleaching solution; if that steeping liquor is then weakened, and an experiment shows it to be of a strength equal to three degrees Twaddell, then to 268 measures of it, 20 measures of stock-bleaching solution will be required to be added to form 288 measures of steeping liquor of the original strength, $\frac{8}{12}^\circ$. In fact, every twelfth of a degree requires four measures of stock solution in the 288 measures of steeping liquid.

CHLORINDOPTIC ACID, *Trichlorophenyllic Acid*, *Chlorophenisisic Acid* ($\text{C}_6\text{H}_3\text{Cl}_3\text{O}_2$), one of the chlorine substitution products of carbolic acid. [CARBOLIC ACID.]

CHLORINE (Cl), an elementary gaseous body discovered by Scheele in 1774 [SCHEELE, BIOG. DIV.], while examining an ore of manganese. He gave it the name of *dephlogisticated marine acid*. By the French chemists, in accordance with the views of Berthollet, it was called *oxygenised muriatic acid*, which was shortened by the English chemists to *oxymuriatic acid*; these latter terms meant that it was a compound of muriatic acid, a supposed elementary or at any rate an undecomposed body, and oxygen. Gay-Lussac and Thénard in 1809 published some experiments from which they inferred that oxymuriatic acid might be a simple substance, but they notwithstanding adhered for a considerable period to the opinion of its being a compound. About the same time Sir H. Davy commenced his examination of the same body, and from his numerous researches he concluded that it ought to be regarded as an undecomposed body; and on account of its colour, he gave this gas the name of chlorine, from $\chi\lambda\omega\rho\acute{o}s$, *green*. Chlorine was first obtained by Scheele, by treating the binoxide of manganese with hydrochloric acid. During the mutual operation of these compound bodies, the oxygen of the binoxide combines with the hydrogen of the acid, and water is formed; the metal of the oxide remains combined with a portion of the chlorine, while the excess which the metal does not unite with is given out in the gaseous state, thus:—

At the present day the above process is largely adopted, on account of the cheapness of hydrochloric acid, which is obtained as a bye-product

in the manufacture of carbonate of soda from chloride of sodium (common salt). [SODIUM, *Compounds of.*]

Chlorine may also be obtained directly from chloride of sodium by heating four parts of the latter with three parts of powdered black oxide of manganese and seven parts of concentrated sulphuric acid, previously diluted with an equal weight of water. The decomposition that occurs is expressed in the following equation:—

Chlorine has a very powerful and disagreeable odour, is very suffocating, even when considerably diluted with air, and its taste is astringent. According to Davy, 100 cubic inches weigh between 76 and 77 grains at the average temperature and pressure, and with this determination the experiments of Gay-Lussac and Thénard nearly agree; its specific gravity is consequently about 2.47. Mr. Faraday found that when this gas is subjected to a pressure of about four atmospheres, and kept cool, it is condensed into a yellow limpid fluid, which is extremely volatile, and which, when the pressure is removed, rapidly reassumes the gaseous form; its specific gravity is about 1.33; its refractive power is less than that of water; and it is a non-conductor of electricity. Cooled to -220° it still remains liquid.

Chlorine gas is absorbed and dissolved by water, and when this fluid has been recently boiled, it will take up twice its bulk of the gas at common temperatures and pressure: the aqueous solution has the colour, smell, and taste of the gas itself. The equivalent of chlorine is 35.45, and when moist chlorine gas is exposed to a temperature of 32° Fahr., yellow crystals are formed, which are *hydrate of chlorine*, consisting, according to Mr. Faraday, of very nearly 1 equivalent of chlorine = $35.45 + 10$ equivalents of water = 90. Neither light, heat, nor electricity, produces any change in the properties of chlorine gas, provided it be dry; but if it be moist, then light causes it to decompose the water, the hydrogen of which combines with it to form hydrochloric acid, while the oxygen is evolved in the gaseous form, and it was this experiment which chiefly induced Berthollet to adopt the opinion of its nature which has already been explained. In the decomposition of the compounds which contain it, it is evolved like oxygen at the positive pole, or anode; except when separated from oxygen, and then it goes to the negative or cathode.

One of the most curious and important properties of chlorine is the power which it possesses of destroying the colour of animal and vegetable matter in general, and hence its extensive application to the purpose of bleaching. [CHLORIMETRY.] When acids alter vegetable colours, they may in many cases be restored by the application of an alkali; but so complete is the destructive power of chlorine, that nothing whatever can reproduce the colour which it has removed. This power appears to depend upon the great affinity which exists between chlorine and hydrogen, the latter element being removed from the coloured compounds to form hydrochloric acid with the chlorine, while more chlorine takes the place of the hydrogen and colourless compounds result.

Chlorine gas is a supporter of combustion. If certain metals, and especially antimony, in the state of powder, be thrown into chlorine gas, they burn spontaneously; phosphorus also exhibits similar phenomena.

Chlorine is also a powerful disinfectant; for this purpose it was first employed by Guyton de Morveau; compounds of chlorine, and lime or soda, have been extensively used for this purpose.

Chlorine is in general easily detected by its odour and colour, whether in its gaseous state or in solution in water. It occasions a white precipitate in solution of nitrate of silver, which speedily darkens by exposure to light. This compound is called chloride of silver. It is insoluble in nitric acid, even when boiled, but is readily soluble in solution of ammonia. By this test, however, a portion only of the chlorine is thrown down; part of it uniting with the oxygen of the oxide of silver forms chloric acid, of which we shall presently make mention. It will be observed from the above statement that those compounds which contain chlorine are called chlorides; but this is the case only when such compounds do not possess acid properties.

Chlorine combines with almost every other elementary body, forming compounds of great importance; we shall first state the nature of those to which it gives rise by uniting with oxygen.

Oxygen and Chlorine combine in several proportions, but the combination is never immediate; and different views of the number and nature of the compounds are entertained by different chemists. The important ones are five in number,—

Hypochlorous acid	ClO
Chlorous acid	ClO ₂
Peroxide of chlorine	ClO ₃
Chloric acid	ClO ₄
Perchloric acid	ClO ₅

The other oxides of chlorine are probably merely compounds of those just enumerated with each other. Thus *euchlorine*, discovered by Sir Humphry Davy, a yellow explosive gas evolved when a chlorate is gently heated with hydrochloric acid, is a mixture of chlorine with *chlorochloric acid* ($2\text{ClO}_3, \text{ClO}_5$).

Chloric Acid (ClO_3).—It has been already mentioned that oxygen and chlorine do not combine by direct action; when however chlorine meets with nascent oxygen they unite. If chlorine gas be passed into water containing oxide of silver diffused through it, a portion of the chlorine combines with the silver and forms a chloride, which is precipitated; and the oxygen expelled from it uniting with another portion of chlorine, constitutes chloric acid, which remains in solution. Any excess of chlorine is to be expelled by heat. Or chloric acid may be made by adding dilute sulphuric acid to chlorate of baryta, in which case sulphate of baryta is precipitated, and chloric acid remains in solution. It is a colourless inodorous acid, which has a sour taste, and reddens vegetable blue colours. The solution may be concentrated by a gentle heat till it acquires an almost oily consistence; it has then a yellowish tint, a peculiar odour, and it sets fire to dry vegetable matters. It combines with bases to form salts termed *chlorates*, which were formerly known by the name of oxygenised muriates, or hyper or oxymuriates. Bodies which have a strong affinity for oxygen decompose chloric acid, by separating that element; thus sulphurous acid is converted into sulphuric acid by decomposing it, and taking its oxygen. Chloric acid is composed of—

$$\begin{array}{rcl} 1 \text{ equivalent of chlorine} & = & 35.45 \\ 5 \text{ equivalents of oxygen} & = & 40 \\ \hline & & 75.45 \end{array}$$

The chlorates, except that of potash, are not important salts: this however is used for many purposes; thus when it is heated it evolves very pure oxygen gas, and chloride of potassium remains; the oxygen is yielded both by the acid and the alkali. Chlorate of potash [POTASSIUM] is prepared on the large scale by passing chlorine gas into a solution of the alkali; part of the chlorine takes oxygen from part of the potash and forms with it chloric acid, which unites with the remainder of the potash to form the chlorate, while the remainder of the chlorine unites with the potassium to form chloride; both salts dissolve in water, but the chlorate crystallises first, and in rhombic plates. This salt detonates when triturated with sulphur; and when struck with phosphorus it explodes and inflames, and in both cases it yields oxygen.

Chlorate of potash is composed of—

$$\begin{array}{rcl} 1 \text{ equivalent of chloric acid} & = & 75.45 \\ 1 \text{ equivalent of potash} & = & 47.0 \\ \hline \text{Equivalent} & & 122.45 \end{array}$$

Chlorate of Baryta (BaO, ClO_3) is extensively used in the manufacture of fireworks.

Perchloric Acid (ClO_4) is procured by the partial decomposition of the chloric acid just described. It is obtained by mixing sixty grains of chlorate of potash with about four times its weight of sulphuric acid, and heating the mixture below 212° in a porcelain basin; a gas, which we shall presently describe, is given out, and there remains in the retort a mixture of bisulphate and perchlorate of potash; by washing with cold water the bisulphate is dissolved, and the perchlorate remains. When this salt is mixed in a retort with half its weight of sulphuric acid diluted with one third of water, and the mixture is heated to about 280° , the white vapour which arises is perchloric acid, which condenses in the receiver.

This acid is a limpid colourless liquid, has a sharp taste, and reddens litmus paper, without destroying its colour. When concentrated by evaporation its specific gravity is 1.65, and it then emits vapour when exposed to the air; it boils at 392° , and rapidly absorbs moisture from the atmosphere. When mixed with sulphuric acid and heated, the acid is distilled, and it concretes on cooling into a solid, which crystallises in prisms. It appears to be the most stable of all the compounds of chlorine and oxygen, not suffering decomposition either by the action of light, sulphurous, or hydrosulphuric acid; it dissolves iron and zinc, with the evolution of hydrogen gas.

The salts formed by this acid with bases are termed *perchlorates*: they are decomposed by heat, yielding much oxygen gas, and are converted into chlorides. The perchlorates are not an important class of salts.

Peroxide of Chlorine, or *Hypochloric Acid* (ClO_2) is a gaseous compound evolved during the formation of perchlorate of potash just described. This gas has a green colour; it has no smell of chlorine, but, on the contrary, an aromatic odour; it is readily dissolved in water, to which it imparts its own colour; the solution does not combine with alkalis; it destroys most vegetable blue colours without previously reddening them. When heated to 212° this gas explodes violently, emits a strong light, and the residual gases occupy more space than the compound did which they formed; 40 volumes of the gas becoming 60, of which 40 are oxygen and 20 chlorine.

The changes which occur in thus preparing perchlorate of potash and peroxide of chlorine are these: the sulphuric acid decomposing a portion of the chlorate of potash evolves chloric acid, which, at the moment of its liberation, is separated into oxygen and peroxide of chlorine; the oxygen combines with the chloric acid of the undecomposed chlorate, and converts it into perchloric acid, and consequently perchlorate of potash is formed, while the peroxide of chlorine, as

already noticed, is evolved in the gaseous state. When three equivalents of chlorate of potash are acted upon by sulphuric acid, there are produced two equivalents of peroxide of chlorine and one equivalent of perchloric acid.

By substituting oxalic acid for sulphuric acid, Messrs. Crace Calvert and E. Davis assert, that peroxide of chlorine may be prepared with far greater facility and much less danger. One equivalent of chlorate of potash (122.5 parts) and nine equivalents of crystallised oxalic acid (567 parts), well powdered and intimately mixed, furnish, when heated in a water-bath to a temperature of 158°, a steady stream of the gas, chloride of potassium and an acid oxalate of potash being left in the vessel. The peroxide of chlorine thus produced, however, always contains carbonic acid.

Chlorous Acid (ClO_2) is a dangerously explosive yellowish green gas, evolved when chlorate of potash, arsenious acid, and nitric acid are gently heated together. It possesses considerable bleaching powers, and forms definite salts, *chlorites*, with bases.

Hypochlorous Acid (ClO). This acid is thus obtained: add finely powdered peroxide of mercury, mixed with twelve times its weight of distilled water, to chlorine gas in a bottle, and shake it well; the oxide of mercury should be slightly in excess, so that when the absorption of the chlorine, which goes on rapidly, is over, the residue should have a reddish rather than a white colour. The whole contents of the bottle are to be put in a filter, upon which there remains oxychloride of mercury, while the filtered liquor, when distilled in vacuo, yields weak hypochlorous acid, which may be concentrated by redistillation.

Hypochlorous acid thus procured is a transparent slightly yellow-coloured fluid; its smell is penetrating and very distinct from that of chlorine or the peroxide; its taste is extremely strong but not acid. When prepared by passing dry chlorine over dried precipitated peroxide of mercury, and condensing the gaseous product by aid of a freezing mixture, it presents the appearance of a deep red liquid, which boils at 68°. It attacks the epidermis with great activity, even more so than strong nitric acid, and imparts a brown stain to the skin. It is a very unstable compound, decomposing probably even at common temperatures. In hot weather it can be preserved for a few days only, without immersion in ice; when weaker and kept from the light, it may be preserved for a longer time. During decomposition it gives out small bubbles of chlorine gas, and some chloric acid is formed, and this decomposition is accelerated by agitation with angular bodies: it is decomposed by the action of light as well as by that of heat.

When to a concentrated solution of hypochlorous acid an equal bulk of solid dry nitrate of lime is added, a brisk effervescence is produced, which is owing to the separation of pure hypochlorous acid gas, which has the following properties: its colour is very little deeper than that of chlorine; its smell is penetrating like that of the solution; it is completely absorbed by mercury, which is transformed into a red oxychloride. It is best prepared by passing up a little of the gas at a time into a jar filled with and inverted in mercury; the nitrate of lime which is dissolved prevents the action of the liberated gas upon the metal: water dissolves nearly 100 times its volume of this gas; it is decomposed by heat with explosion. The fixed alkalies and the alkaline earths combine with hypochlorous acid.

The hypochlorite of lime, usually called chloride of lime, or bleaching powder, is a compound of great importance, both in the arts and as a disinfectant. [CALCIUM.] The exact composition of this compound is a subject still under discussion. Another compound, the nature of which is perhaps more problematical, is that formed by passing chlorine gas into a solution of carbonate of soda; the gas is plentifully absorbed without evolving any carbonic acid. This compound, like the hypochlorite of lime, is used as a disinfectant, under the name of Labarraque's soda liquor. With regard to the composition of the substances formed when chlorine is absorbed by the bases, chemists usually hold one of two opinions. First, that a double salt is formed, consisting of a chloride of the metal and a hypochlorite of the oxide of the metal, thus,—

Second, that the chlorine unites directly and simply with the oxide of the metal, and that the so-called double salt merely consists of two equivalents of such a body, thus,—

The second view is the more probable one.

Nitrogen and chlorine combine to form the

Chloride of Nitrogen. This compound was discovered by Dulong in 1811. These gases do not combine by direct action, but when chlorine gas meets nitrogen gas in the nascent state they unite. It may be prepared by dissolving an ounce of chloride of ammonium in twelve to sixteen times its weight of water, and then inverting a bottle of chlorine gas in the solution. The chlorine is gradually absorbed, and there are formed small drops of an oil-like fluid which sink in the

solution: these are the chloride of nitrogen, derived from the combination of the chlorine with the nitrogen of the ammonia.

The properties of this substance are that it is extremely explosive, sometimes detonating spontaneously, but always on the contact of fatty matter, phosphorus, and various other bodies. Its specific gravity is 1.653. It is not solidified by the most intense artificial cold. At 160° it may be distilled, but at 200° to 212° it explodes.

Chlorine and hydrogen combine to form the

Hydrochloric Acid (HCl), sometimes called *muriatic acid* and *spirit of salt*. When equal volumes of these gases are mixed and kept in the dark, they do not unite, but if exposed to daylight they combine slowly, and by the direct rays of the sun, the electric spark, or a taper, they unite with explosion, and there is formed a quantity of hydrochloric acid equal in volume to that of the two gases employed. As 50 cubic inches of hydrogen weigh 1.07 grain and 50 of chlorine 38.57 grains, their combined weight gives that of 100 cubic inches of the gas = 39.64 grains, or its specific gravity is 1.2474. This gas is colourless, has a very pungent odour, and an acid and acrid taste. It excites coughing, unless largely diluted with air; extinguishes burning bodies when they are immersed in it; and reddens vegetable blue colours strongly. By heat it is merely expanded, but by electricity it is decomposed. Under a pressure of forty atmospheres at 50°, it condenses to a colourless liquid, which the most intense cold does not solidify. The affinity of this gas for water is so great, that when it escapes into the air, it forms a white vapour by combining with atmospheric moisture; water absorbs 400 times its bulk of this gas, and the result is liquid hydrochloric acid, usually called hydrochloric acid.

As this acid is largely employed, it is prepared in a more economical manner than the direct formation of the gas, by decomposing common salt with sulphuric acid. For this purpose, 24 parts of common salt, termed chemically chloride of sodium, are mixed in a retort with 20 parts of sulphuric acid, and 12 of water, and into the receiver an equal quantity of water is put; by distillation to dryness, a colourless acid is obtained, which has a specific gravity of about 1.16.

For manufacturing purposes this process is usually conducted in iron vessels, and the product condensed in a series of stoneware (Woulfe's) bottles, or by conducting the gas through tall columns or towers filled with coke, down which a small current of water is made to trickle. The acid thus produced, though very strong, always contains a considerable quantity of iron and other impurities in solution, and is, therefore, always more or less coloured.

During the mutual action of the salt, acid, and water, a portion of the water is decomposed, which yields hydrogen to the chlorine, and these form hydrochloric acid, while its oxygen unites with the sodium, to form soda, which with the sulphuric acid constitutes sulphate of soda, which remains in the retort. This solution of hydrochloric acid has the smell and acid properties of the gas itself; it emits white fumes, and reddens litmus paper. It dissolves many metals, such as iron, zinc, and tin, and forms with them chlorides, the acid being decomposed and yielding hydrogen gas during their solution. These compounds will be treated of as chlorides, under the respective metals. Hydrochloric acid is largely employed in the arts connected with, or dependent upon, chemical operations, as in dyeing and calico printing, and in making chloride of ammonium or sal ammoniac [AMMONIA]; it unites also with the vegetable alkalies, as morphia, quinine, &c., to form hydrochlorates; but with metallic oxides, it forms chlorides, and not hydrochlorates, on account of the decomposition which it suffers, as just explained. When mixed with the nitric acid also, it is decomposed, and a solution is obtained, which is used under the name of *aqua-regia*, or *nitro-muriatic acid*, or *nitro-hydrochloric acid*, for dissolving gold and platinum.

The strength of commercial hydrochloric acid is most readily ascertained by taking its specific gravity. The following table, slightly abridged from one drawn up by Dr. A. Ure, shows the per centage of hydrochloric acid gas in aqueous hydrochloric acid:—

Sp. gr.	Per cent.	Sp. gr.	Per cent.	Sp. gr.	Per cent.
1.200	40.77	1.158	31.81	1.112	22.83
1.198	40.37	1.155	31.39	1.110	22.42
1.196	39.96	1.153	30.99	1.108	22.02
1.194	39.55	1.151	30.58	1.106	21.61
1.193	39.14	1.149	30.17	1.104	21.20
1.191	38.74	1.147	29.76	1.102	20.79
1.189	38.33	1.145	29.36	1.100	20.29
1.187	37.92	1.143	28.95	1.098	19.98
1.186	37.52	1.141	28.54	1.096	19.57
1.185	37.11	1.139	28.14	1.094	19.16
1.182	36.70	1.137	27.73	1.092	18.76
1.180	36.29	1.135	27.32	1.090	18.35
1.178	35.88	1.133	26.91	1.088	17.94
1.176	35.47	1.131	26.51	1.086	17.53
1.174	35.07	1.128	26.09	1.084	17.13

Chlorine unites with several of the non-metallic bodies [BROMINE, IODINE, PHOSPHORUS, SELENIUM, and SULPHUR]. Having already given an account of boron and carbon, we shall briefly state the nature of the chlorides of these elementary bodies.

Chlorine and boron form

Terchloride of Boron (BCl_3). It was found by Davy that boron, when recently prepared, burns in chlorine gas; Berzelius remarked that if the boron be previously rendered compact, combustion does not occur until these elements are heated. The resulting compound is a colourless gas, which, when freed from excess of chlorine by means of mercury, has the following properties: it is colourless; its specific gravity is 4.079; it is readily soluble in water, by decomposing a portion of which hydrochloric and boracic acids are obtained: the same effect is produced, accompanied with a white vapour, when the gas escapes into the atmosphere. It combines with ammonia to form a crystalline compound, the nature of which has not been minutely examined.

Chlorine and Carbon form four different chlorides; namely, the dichloride, protochloride, sesquichloride, and bichloride. No combination can be effected between these elements by direct action; carbon, even heated to whiteness in the gas, does not form any compound with it. The discovery of several of these compounds is due to Mr. Faraday. ('Phil. Trans.' 1821.)

The *dichloride of carbon* (C_2Cl_2) is obtained from protochloride of carbon, by causing the latter to pass several times through a tube heated to bright redness. It occurs in small soft colourless fibres; it fuses when heated, and at 250° sublimes and condenses unchanged. It is insoluble in water, acid, and alkalies, but may be dissolved in hot oil of turpentine and in alcohol, recrystallising as the solutions cool; it burns with a red flame, yielding much smoke and hydrochloric acid vapour.

The *sesquichloride of carbon* (C_2Cl_6) which it will be most convenient, although not in strict order, to consider next, is formed when olefiant gas, a compound of hydrogen and carbon [CARBON], is mixed with chlorine; they combine to form an oil-like liquid which is composed of chlorine, carbon, and hydrogen; by exposure to the direct rays of the sun, hydrochloric acid and sesquichloride of carbon are formed by its decomposition.

This chloride is solid; its smell is rather aromatic; it is a non-conductor of electricity; its specific gravity is 2. It melts at 320° , and at a higher temperature may be distilled without suffering any change; water dissolves it but sparingly; it is soluble in alcohol, ether, and the fixed and volatile oils. Its vapour density is 8.157.

It burns when strongly heated, but is not acted upon either by acids or alkalies; when passed with hydrogen through a red-hot tube, hydrochloric acid is formed and carbon deposited.

The *protochloride of carbon* (C_4Cl_4) is obtained by passing the sesquichloride in vapour through a red-hot porcelain tube; chlorine gas escapes in such proportion as to reduce the sesquichloride to a protochloride, which is a limpid colourless liquid of specific gravity 1.552: it is not solidified at 0° Fahr. Its boiling point is 248° , and the specific gravity of its vapour 5.820. When repeatedly distilled it suffers no change.

The *bichloride of carbon* (C_2Cl_4) is best formed by passing chlorine through bisulphide of carbon, and the mixed vapours through a porcelain tube heated to redness. On condensing and purifying by washing and distillation, it is obtained as a limpid colourless liquid of specific gravity 1.599; boiling point 172° ; vapour density 5.30. Cooled to -9° it solidifies to a mass of pearly crystals.

CHLORINE, Medical Uses.—When pure and concentrated, chlorine is very deleterious; it acts as an irritant poison. Its action is most violent and speedy when it is brought into contact with the respiratory organs; it then occasions such violent spasms of the glottis, or opening of the windpipe, that instant death may ensue. To enable chlorine to pass this orifice it must be very largely diluted with atmospheric air, or aqueous vapour. A strong solution of it introduced into the stomach causes irritation, inflammation, and death; and even a stream of the gas, or aqueous vapour of it, directed upon the skin, will cause a pricking or stinging sensation, followed by an eruption of pimples or even vesicles. Notwithstanding its formidable properties, it has been used in several cases with such success that no adequate substitute can be found for it. As a disinfecting agent, or means of decomposing and rendering innoxious putrid miasmata, and other sources of disease, it is unrivalled. For this purpose it may either be directly mingled with the air of the infected place, by preparing it on the spot, or by means

of one of Morveau's disinfecting bottles; or it may be gradually liberated from some of its combinations, such as the chloride of soda or lime. This last method is best when human beings remain in the apartment; but the former is preferable, when they have been removed, for purifying the wards of hospitals, cells of gaols, or holds of ships. When not in a very concentrated form, the respiratory organs become habituated to breathing it, and the workmen in manufactories where it is used enjoy a marked immunity from epidemic fevers, and attain a considerable age.

From having been observed to allay chronic cough existing among the workmen of certain manufactures, it has been proposed to be inhaled in a diluted state in several chronic affections of the lungs, such as asthma, chronic bronchitis, and even phthisis pulmonaris, or consumption. In the two former it is of some utility, in the latter it is a mere palliative, but is attended with the advantage of destroying the fœtor of the breath, which is distressing both to the patient and attendants. The chlorine employed in this way must be extremely pure, the preparation frequently renewed, of uniform strength of $1\frac{1}{2}$ volume of chlorine in solution, and carefully preserved from the sunlight, which decomposes it. It may be breathed in a small quantity out of a proper apparatus four or five times a day.

A weak solution of chlorine has been employed, introduced into the stomach, with considerable success in indigestion, with loss of appetite, loaded tongue, and foul taste in the mouth.

Its employment in the form of a bath is not common, but occasionally useful, from its irritant effect on the skin. It is doubtful whether it possesses the specific effect upon the liver which some ascribe to it.

In case of poisoning by the gas, inhaling ammonia or sulphuretted hydrogen in small quantity is useful. Should an overdose of the solution be swallowed, chalk, magnesia, or other alkali, or white of egg in water, or a draught of milk, would be proper as an antidote. On the opposite hand, chlorine is said to be a valuable antidote in case of poisoning by hydrocyanic (prussic) acid, sulphuretted hydrogen, or hydrosulphate of ammonia.

CHLORIODIC ACID, Chloride of iodine, a compound of chlorine and iodine, which on account of its acid properties was termed an acid by Davy, but by Gay-Lussac simply *chloride of iodine*, he being of opinion that the acidity of its solution arises from the presence of hydrochloric and iodic acids, generated by the decomposition of water.

Iodine, when dry, absorbs chlorine at common temperatures with the evolution of heat: when the iodine is perfectly saturated with chlorine, the compound is orange-yellow, but reddish-orange if the iodine be in excess. By heat it is converted into a yellow-coloured liquid, yielding a vapour of the same colour when the temperature is increased. It is deliquescent, readily soluble in water, and forms a colourless solution which is very sour to the taste, first reddens and then destroys vegetable blue colours. It probably consists of 1 equivalent of chlorine and 1 equivalent of iodine.

CHLORIDOFORM (C_2HCl_3). This body, which may be regarded as chloroform, in which one equivalent of chlorine has been replaced by iodine, is obtained by heating iodoform with bichloride of mercury. It is a yellow liquid of an aromatic odour, and a specific gravity of 1.96.

CHLORISATHYDIC ACID, a chlorinated substitution product derived from indigo.

CHLOROCARBOHYPOSULPHURIC ACID. [TRICHLORMETHYLSULPHUROUS ACID.]

CHLOROCARBONIC ACID GAS, Oxychloride of Carbon (COCl_2) This acid, called by Dr. Davy, who discovered it, *phosgene gas* (from *phôs*, light, and *γεννᾶν*, to produce), was formed by exposing a mixture of equal volumes of dry chlorine and carbonic oxide gases to the solar rays; combination takes place rapidly, but without explosion, and they contract to half their bulk; day-light produces the effect slowly, but in the dark it does not take place at all.

Chlorocarbonic acid gas is colourless, has a strong smell, and reddens litmus paper even when dry; it decomposes water, and there are formed hydrochloric and carbonic acids. Several metals when heated in it decompose it; they are converted into chlorides, and carbonic oxide is evolved. The specific gravity of this gas is 3.68. When mixed with ammoniacal gas it condenses four times its volume, and forms chloride of ammonium and carbamide,

CHLOROCHLORIC ACID. [CHLORINE.]

CHLOROCHROMIC ACID. [CHROMIUM.]

CHLOROCINNOSE ($\text{C}_{14}\text{H}_4\text{Cl}_4\text{O}_2$), a compound produced by the action of chlorine upon oil of cinnamon. When pure, it exists in the state of brilliant, colourless, acicular crystals, which fuse and volatilise by heat without change. Even when heated in concentrated sulphuric acid it is not decomposed, nor is it altered by heating in ammoniacal gas. It appears that its formation depends upon the displacement of 4 equivalents of hydrogen from oil of cinnamon by 4 equivalents of chlorine.

CHLOROCYANIC ACID. [CYANOGEN.]

CHLORODRACONESIC ACID ($\text{C}_{10}\text{H}_7\text{ClO}_6$), *chloranistic acid*, a chlorinated substitution product derived from anisic acid. [ANISIC ACID.]

CHLOROFORM (C_2HCl_3), a peculiar compound fluid, obtained about the same time by Soubeyran and Liebig. To procure it, distil a mixture of alcohol and a solution of chloride of lime; separate the product from the liquid distilled with it, shake it with five or six times its volume of concentrated sulphuric acid; pour it off, mix with a little sulphuric acid, distil, and rectify from chloride of calcium.

Chloroform is a limpid fluid; its specific gravity is 1.480; it boils at about 141° Fahr.; does not readily burn, but when a glass rod moistened with it is put into the flame of a spirit lamp, it burns with a yellow sooty flame fringed with green. It is soluble in alcohol and ether; water precipitates it from them; it dissolves iodine, phosphorus, and sulphur; is not decomposed by potassium; but when this metal is heated in its vapour, combustion and explosion ensue, chloride of potassium is formed, and charcoal is deposited. Heated with alcoholic solution of potash, it yields formate of potash.

Pure chloroform, when dropped into water, falls to the bottom without becoming milky. If chloroform contain alcohol it is coloured green when mixed with bichromate of potash and sulphuric acid. Chloroform is the best solvent for caoutchouc and gutta-percha; on the evaporation of these solutions, the gums are left with all their properties unaltered. When gutta-percha is thus treated it becomes white, like ivory.

A large amount of the chloroform now manufactured is made from *methylated spirit*, which if properly treated yields chloroform equal in purity to that furnished by duty-paid alcohol. Chloroform is almost exclusively employed in medicine as an anæsthetic. [METHYL; ANÆSTHETICS.]

CHLOROGENIN. [MADDER, COLOURING MATTERS OF.]

CHLOROGINIC ACID. [CAFFEINE.]

CHLOROMELAL ($C_{120}H_{91}Cl_{25}O_2$?), a resinous body, produced by the action of chlorine upon hydrate of myricyl.

CHLOROMETHYLASE, *bichlorinated ethylene?* ($C_2H_2Cl_2$), an oily product obtained by the action of chlorine upon acetate of methyl.

CHLOROMETHYLSULPHUROUS ACID, *chloromethyldithionic acid* ($C_2H_2ClS_2O_6$), a chlorinated derivative of methylsulphurous acid.

CHLORONICEIC ACID. This acid has recently been proved to be identical with chlorobenzoic acid.

CHLORONICINE. This product, derived from oxyphenic acid, and to which the formula $C_{20}H_{12}Cl_2N_2$ had been assigned, is, in all probability, either identical or isomeric with chloraniline ($C_{12}H_6ClN$).

CHLORONITRIC GAS. [NITROHYDROCHLORIC ACID.]

CHLORONITROUS GAS. [NITROHYDROCHLORIC ACID.]

CHLOROPHANE. [CALCIUM, fluoride of.]

CHLOROPHENISIC ACID. [CHLORINDOPTIC ACID.]

CHLOROPHYLL, *Chromule*. The colouring matter of leaves has been thus named by Pelletier and Caventou. It is obtained by bruising, pressing, and then washing them with water, and afterwards treating them with alcohol, which dissolves the green colour and wax; when water is added to this solution, and the alcohol distilled, the green substance, which contains wax, floats on the surface of the water; when this is heated with ether, the wax is dissolved, and chlorophyll remains nearly pure. When exposed to light, or the action of chlorine, it is bleached. Acids produce a similar effect, and by the alkalis it is converted into soap. The red tint which leaves assume in autumn appears to be owing to the formation and action of an acid; the green colour is restored by an alkali. Its composition is not known.

CHLOROPICRIN, *chloride of perchlorinated nitromethyl* [$C_2Cl_3(NO_4)$], a colourless, transparent oil, obtained by the action of chloride of lime upon picric acid.

CHLORORUBIN. [MADDER, COLOURING MATTERS OF.]

CHLOROSAMIDE, *Hydride of chloronitrosalicyl* ($C_{12}H_{15}Cl_3N_4O_6$). A yellow crystalline product obtained by passing a current of dry ammoniacal gas into hydride of chlorosalicyl.

CHLOROSUCCIC ACID ($C_6HCl_3O_4$?), a chlorinated derivative of succinic acid. [SUCCINIC ACID.]

CHLOROUS ACID. [CHLORINE.]

CHLOROXETHIDE. [OXALIC ACID.]

CHLOROXYNAPHTHALIC ACID. [MADDER, COLOURING MATTERS OF.]

CHOCOLATE AND COCOA. Much confusion arises from the application of the name *cocoa* to two entirely different plants, having no connection whatever with each other. This is the more absurd because the name is not strictly applicable to either; the one being properly *Cocos*, and the other *Cacao*. Again, there is no general appreciation of the difference between *cocoa* and *chocolate*. Referring to the NATURAL HISTORY DIVISION for an account of the botanical characteristics of the respective plants, we shall here briefly notice the commercial distinctions in their relation to manufactured products.

Cocos.—One of the most valuable of tropical trees is the *Cocos nucifera*, the nut-bearing *cocos*, or *cocoa-nut tree*. Scarcely any other tree is applied to so many uses by the natives of the countries in which it flourishes. The roots are chewed in place of the areca-nut; gutters, drains, and the posts of huts are formed from the trunk; the young buds are a delicate vegetable. Shade is furnished by the leaves when growing, and after separation from the tree their large size and hard texture render them invaluable as thatch for cottages; they are, moreover, manufactured into baskets, buckets, lanterns, articles of head-dress,

ARTS AND SCI. DIV., VOL. II.

and even books, upon which writing is traced with an iron stylus. Their ashes yield potash in abundance; their midrib forms oars; and brushes are formed by bruising the end of a leaf with a portion of the midrib adhering to it. From the juice of the stem a kind of palm wine, and subsequently an ardent spirit, are prepared; the farinaceous matter contained in the stem is a good substitute for sago; and a coarse dark-coloured sugar, called *jaggery*, is obtained by inspissating the sap. This *jaggery*, mixed with lime, forms a powerful cement, which resists moisture, endures great solar heat, and will take a fine polish. The ripe fruit is a wholesome food, and the milk it contains yields a grateful cooling beverage; indeed, these together constitute the principal sustenance of the poorer natives in many tropical countries. The fibrous bark is used to polish furniture, as brushes, and to form a valuable elastic bark is cordage called *coir*; the fibrous matter of the husk is also employed to stuff mattresses; and a manufacture of it into cordage, mats, sacking, &c., has sprung up in Great Britain. The shell is made into drinking-vessels and vessels of measure; and, finally, the albumen, or white solid matter contained within the shell, yields by pressure or decoction an excellent oil. This oil is not only employed for burning and for making candles, but in the manufacture of torches, and in the composition of pharmaceutical preparations; and mixed with dammer (the resin of *Shorea robusta*) it forms the substance used in India for caulking the seams of boats and ships. *Cocoa-nuts* are brought to Europe as wedges to set fast the casks and other round packages in the cargo of vessels; their freight therefore costs nothing. They constitute the part of the plant best known in this country, chiefly for its palatable fruit. In reference to manufactures, the nut is more largely valuable, on account of the oil which it contains. In Ceylon, the natives expose the ripe nuts on mats to the heat of the sun, and bring them to a certain state of dryness; they are sent in this state to England, under the name of *copperah*. When the natives express the oil themselves they call the refuse oil-cake by the name of *poonac*; this also finds a market in England. For home purposes the Cingalese do not obtain the oil by pressure; they simply boil the fresh pulp, and skim off the oil as it rises. When they prepare the oil for exportation to England, they expose the *copperah* to the action of a press worked by bullocks, and obtain about two gallons and a half of oil from a hundred average-sized nuts. Steam-power has lately been used to supersede the less effective labour of bullocks. The oil is largely used in the manufacture of candles and soap. A kind of *cocoa-nut butter* is obtained from another species of the tree, the *Cocos fusiformis*, or great macaw tree, in Trinidad, Jamaica, and South America. The nuts are slightly washed, cleansed, and ground to paste in a mill, and then on a stove; the paste is next heated, and mixed with 30 per cent. of its weight of boiling water. The mixture is put into a bag, and pressed between two hot iron plates, by which it is made to yield 75 per cent. of its weight of oil. This oil, when purified by filtration, somewhat resembles butter in appearance, with a golden-yellow colour, an odour of violets, and a sweetish taste. It enters largely into use for toilet soaps. So far as concerns the true *cocoa-nut oil*, it is imported more and more largely every few years: between the years 1845 and 1847, the quantity ranged from 30,000 to 50,000 cwts. yearly; between 1848 and 1852, from 60,000 to 100,000 cwts.; and between 1853 and 1858, from 130,000 to 250,000 cwts. The operations carried on by the Price's Patent Candle Company, at Vauxhall and elsewhere, have effected more than anything else in bringing this kind of oil into use in this country. [CANDLE MANUFACTURE.]

Cacao.—We now come to the plant which really yields the so-called *cocoa* of the breakfast-table, and its off-shoot *chocolate*. The nut, bean, berry, seed, or kernel (for it has been called by all these names) of the *Theobroma cacao* is the part of the plant employed for this purpose. To prevent confounding this with the nut of the *Cocos nucifera* (just described), we will call it a *bean*. The Mexicans call the tree *chocolatl*, and hence the European name for one of the preparations derived from it. If the beans and husks be roasted, and then ground, the result is a pasty mass, which constitutes *cocoa*; or sometimes the nuts are pressed to obtain a certain portion of oil, and then the remaining cake is ground up into paste. As if to increase the confusion above adverted to, the name of *cocoa-oil*, or *cocoa-nut oil*, is often given to this oil, as well as to that obtained from the fruity *cocoa-nut*; but sometimes the better, because more distinctive, name of *butter of cacao* is given to it. To obtain this butter or oil, the beans are confined in strong canvas bags, and pressed by hydraulic machines at a certain temperature; the oil which flows out is agitated or churned with dilute sulphuric acid, then allowed to settle, then skimmed and decanted, and lastly filtered. It is used as oil for lamps, and as a substitute for cod-liver oil in medicines. *Cacao stearine* is produced from the cake which remains when the oil has been pressed out by steaming, dissolving, settling, and cooling; it is combined with other fatty matters in making soap and candles.

The *cocoa* prepared as a beverage is, as we have said, made either from the roasted and ground beans or from the oil-cake. A cheap and common kind is made from the oil-cake of damaged beans, mixed with flour, meal, suet, fat, &c.; it can be sold as low as 4d. or 6d. per lb. *Flake cocoa* consists of roasted and ground beans compressed into a hard substance, and then sliced or flaked by a machine. *Soluble cocoa* consists of the bean ground fine, and mixed with sugar and meal to render it more soluble in water. In roasting the beans for converting the *cacao*

into *cocoa*, care is taken to stop the roasting as soon as the aroma is developed; they are then turned out, cooled, and husked. On a large scale, the roasting and husking are conducted by the aid of well-constructed machinery; on a small scale, a common frying-pan would suffice for the roasting, if care were taken in the process. Dr. Lindley, in a lecture on the results of the Great Exhibition of 1851, said: "We have the evidence of one of the most skilful brokers in London, who has had fifty years experience to enable him to speak to the fact, that we never get good cocoa in this country. The consequence is, that all the good chocolate is made in Spain, France, and the countries where the fine description of cocoa goes. We get cocoa which is unripe, flinty, and bitter, having undergone changes that cause it to bear a very low price in the market." He showed that differential duties had had something to do with this, and then proceeded: "Still, it appears to me, that we might supply from our own colonies this very cocoa. There was exhibited, from Trinidad, a very beautiful sample, quite equal to anything produced in the best markets of the Magdalena, and of other places on the Spanish Main. It had no bitterness, no flintiness, no damaged grain in it; but all were plump and ripe, as if they had been picked. The cocoa from the Spanish Main [South America?] goes into other countries for the preparation of that delicious chocolate which we buy of them."

Chocolate.—Chocolate is nothing more than breakfast-cocoa carried to a little further stage of preparation. The Mexicans, to whom its name is due, are said to prepare it better than it is usually prepared in England. They roast the cocoa-beans in an iron pot pierced with holes; then pound them in a mortar, grind the powder to a paste between two stones, sweeten the paste with sugar, and add to it one or two of the following ingredients: long pepper, annatto, vanilla, cinnamon, cloves, aniseed, musk, or ambergris. The Spaniards flavour their chocolate with vanilla, cloves, and cinnamon, and often scent it with musk and ambergris, in the Mexican fashion; this is then called *Spanish chocolate*. The *French chocolate* is made from the best Caraccas beans, a good deal of refined sugar, and a little vanilla. In England we have a large variety of prepared chocolates, under the names of *medicated*, *hygienic*, *homœopathic*, *aromatic*, *chalybeate*, *purgative*, *jalap*, *scammony*, *vermifuge*, &c.—all deriving their distinctive qualities from the addition of certain drugs or pharmaceutical preparations to the chocolate.

Like many other articles of prepared food, cocoa and chocolate are often disgracefully adulterated with nearly worthless substances, to enable fraudulent dealers to undersell their neighbours. Chemists have discovered, by careful analysis, starch, treacle, flour, potato-meal, sago-meal, and colouring earthy matter, mixed up with various samples of cocoa and chocolate sold in the retail shops of London.

Cocoa is now so highly prized, both as a pleasant and as a nutritious beverage, that physicians recommend it as a portion of the dietaries for soldiers, sailors, emigrants, invalids, &c.; and English private families largely use it.

CHOIR is, according to the common acceptation of the word, that part of a cathedral, between the chancel and screen, in which divine service is performed; it is separated from the nave by the screen, over which the organ is, in England and Ireland, very commonly placed. But the word is now frequently employed by writers on Gothic architecture in the same sense as chancel: that is, to designate that part of a church, whether cathedral or parochial, eastward of the nave, in which the service of the communion is performed.

The choir is also the term by which the lay-vicars, or lay-clerks, and choristers, that is, the singers, of a cathedral, are collectively designated. Their number in each cathedral varies, in most cases in proportion to the degree of integrity possessed by the respective dean and chapter at the Reformation, and subsequently. But, generally, the dignitaries contrived to retain as scanty a portion as possible of the musical members of the church. The choral service in the English churches had been much neglected, but it is now generally performed in a far more reputable and decorous manner than was the case forty or fifty years back; in most of our cathedral, and in many parish churches, the choral service is now very efficiently performed. The Exeter Hall performances, and the Handel Festivals at the Crystal Palace (1857 and 1859), have had much influence in spreading a taste for sacred music.

CHOKER DAMP. [CARBONIC ACID.]

CHOLACROL ($C_{16}H_{10}(NO_4)_2O_{10}$), one of the products of the oxidation of choloidic acid with hot nitric acid. It is a heavy oily body, found at the bottom of the receiver containing the products of condensation. It is purified by washing with water, in which it is insoluble. Alcohol and ether dissolve it with facility. It has a very acrid odour. For the other product of condensation, see **NITROCHOLIC ACID**.

CHOLALIC ACID ($C_{48}H_{40}O_{10}$), produced by the action of alkalis on cholic acid or choleic acid. The acids are boiled for a long time with solution of potash, or, better, baryta water; the concentrated liquid then deposits a crystalline mass, which may be decomposed by hydrochloric acid, and the residue, after evaporation nearly to dryness, dissolved in alcohol and recrystallised. From solution in alcohol, it separates in tetrahedra or octohedra, and from water in rhombic tables.

Cholalic acid decomposes soluble carbonates with effervescence, and combines with most bases to form salts, some of which are crystalline.

CHOLEIC ACID ($C_{52}H_{46}NO_{14}S_2$), (*Sulphocholeic acid*; *Taurocholic acid*; *Taurocholalic acid*). Of the two acids that, combined with soda,

occur in ox-bile, choleic acid is alone the one that contains sulphur. It is also less abundant than cholic acid, the other constituent, but in the bile of serpents and fishes is by far the principal ingredient. It is best prepared by precipitating aqueous solution of ox-bile, first with neutral acetate, and then with subacetate of lead, till clear, white, plaster-like precipitates are obtained. The filtered liquid will now give with subacetate of lead and free ammonia a precipitate consisting almost exclusively of choleate of lead. This compound is washed with water, dissolved in alcohol, and reprecipitated by water; twice or thrice treated in a similar way; and finally decomposed by passing sulphuretted hydrogen through water, in which it is suspended. The filtered solution, by evaporation to dryness, yields choleic acid as a grayish-white mass.

Boiled with alkalis, it is decomposed into cholalic acid, mentioned above, and *taurin* [TAURIN], thus:—

Choleic acid forms, with the alkalis, salts, soluble in water and alcohol. With baryta, it forms a crystalline combination. It gives a purple colouration with sugar and sulphuric acid, similar to that produced by cholic acid.

CHOLEPYRRHIN. The brown colouring matter of human bile. It is readily altered by re-agents. The alteration in colour produced by nitric acid has been proposed as a method of detecting bile in urine, which, if bile be present, becomes first green, then blue, and finally violet, when nitric acid is added to it.

CHOLERA, from *χολή* and *ῥέω*, signifying *bile-flux*, a disease which has derived its name from its supposed cause, a preternatural quantity and a morbid quality of the biliary secretion.

The first symptom of this malady commonly consists of griping pains of the bowels; these are soon followed by vomiting and purging: there is always a redundancy and an altered condition of the bile, and, in some cases, after the vomiting and purging have continued for some time, there supervene spasms in different parts of the body, but particularly in the upper and lower extremities, and more especially in the legs. The tongue is usually dry, the thirst urgent, and the urine scanty. The pulse, at first free and frequent, as the disease advances becomes smaller and weaker, and the strength is very rapidly reduced. This form of the disease is commonly termed *bilious cholera*.

The chief exciting causes of this malady appear to be particularly connected with temperature. It rarely if ever attacks in the spring, at least in this country, while it is seldom altogether absent in the latter part of summer, and particularly when summer is passing into autumn. Hence its exciting cause would appear to be not so much a high temperature as an alternation of temperature from heat to cold, such an alternation constantly taking place at this season of the year, and occurring every day, in the great difference that takes place between the temperature of the day and that of the night. Accordingly this disease is observed to be by far the most frequent and the most severe at the seasons when those alternations are the most remarkable; when, for example, cold easterly or northerly winds suddenly set in after hot weather, and, above all, when this cold is combined with a moist atmosphere, as "during very warm summers and autumns occurring after a very rainy winter and spring, or after a succession of wet seasons, and when the days have been warm, bright, and sunny, and the nights cold with heavy dews." When such a concurrence of circumstances takes place in a high degree, the disease becomes so prevalent as to be as truly epidemic as any of the forms of fever common to the climate.

It is generally conceived that the use of certain kinds of fruit which abound at this season, as cucumbers and melons, and certain vegetables, as peas and the undressed vegetables used in salads, are powerful concurrent causes. In persons very much predisposed to this malady, such articles of diet may co-operate with the season to produce it; but when the state of the season is such as to render the disease epidemic, it attacks numbers of persons who never use food of this kind. Animal food of a bad quality or too long kept, as animal food of all descriptions is very apt to be at this season of the year, is a much more powerful concurrent cause. So also is excess of food, though of the best quality, and intemperance in the use of malt, vinous, and spirituous liquors; together with whatever causes tend to diminish the vital energies, and so to lessen the power of resistance inherent in the body to the influence of noxious agents.

There is reason to believe that certain poisonous particles of matter, derived from decayed vegetable and animal substances, and diffused in the atmosphere, are among the most powerful exciting causes of cholera, as it is certain that they are of fever. Hence it has been observed that to certain districts in some southerly climates, particularly between the tropics, bilious cholera may be said, from the frequency of its occurrence, to be strictly endemic, although in a less marked degree than certain forms of fever or dysentery. "According to my own observation," says Dr. Copland, "and that of several friends whose range of experience has been great, bilious cholera is very prevalent in situations which are subject to emanations from decayed vegetable matter, or putrid matter of any description, particularly from swamps, moist ground, the banks of rivers, lakes, or canals, &c., and from foul

drains or cesspools, during warm seasons, or wide and rapid changes of temperature; or when the thermometer rises high during the day, and sinks low towards the night and morning."

The presence of these miasmata as the cause of cholera accounts for the much greater prevalence and severity of this disease, in this country, in ancient than in modern times. The account given by Sydenham, who wrote about the middle of the 17th century, of the regular annual return of cholera and of its great fatality, may well make us rejoice at the altered condition as to cleanliness of our streets, drains, and houses, and at the different kind and better quality of our food.

"This disease," says Sydenham, writing of cholera as it appeared in London in the year 1699, "comes as certainly at the latter end of summer and at the approach of autumn as swallows at the beginning of spring, and as cuckoos at the heat of the following season. That disease which is occasioned by a surfeit comes at any time; the symptoms are indeed alike and the cause the same, yet it is of another kind. The cholera is easily known, for there are violent vomitings and an evacuation of ill humours with great difficulty and trouble by stool: there is a violent pain and inflammation of the belly; a heart-burning, thirst, a quick pulse with great anxiety, and often a small and unequal pulse with great nausea and sometimes a colliquative sweat, contractions of the arms and legs, fainting, a coldness of the extreme parts, and such-like symptoms, which frighten the bye-standers and kill the patient in twenty-four hours."

The persons most liable to bilious cholera are either those whose bowels are preternaturally irritable, and who are consequently subject to diarrhoea, or those whose bowels are torpid, and who are consequently subject to habitual constipation. In the latter case it is probable that the biliary secretion is sometimes long retained in the gall-bladder, where it becomes changed in nature, and acquires irritating properties.

Bilious cholera is rarely fatal in this country, excepting at seasons when the concurrence of circumstances is peculiarly favourable to the production of a severe form of the disease, and when at such seasons it attacks persons very much predisposed to it, and whose constitutions have been previously enfeebled by other causes. Its ordinary duration is from twenty-four hours to three or four days, when it often spontaneously disappears; but in general medical aid is indispensable; and when the attack is severe, if such aid be not promptly afforded, the danger of the disease and the difficulty of the cure are very seriously increased.

The milder forms of bilious cholera may pass away without the occurrence of any degree of spasm; but when the attack is severe, spasm is as constantly present as vomiting or purging. And cases now and then occur in which the spasm comes on so early and is so prominent as to give its own name, *spasmodic cholera*, to the disease. Spasmodic, by no means as frequent as bilious cholera, is on the other hand a much more formidable malady. It is indeed the same in nature, and arises from precisely the same causes, but its intensity and danger are widely different. Its attack is often immediately preceded by a sense of chilliness or a distinct rigour; the griping pains are more severe than in bilious cholera; the vomiting and purging are more urgent; the matter rejected consists of a watery or slimy fluid, and very soon there come on painful and violent spasms, which attack the muscles of the abdomen, thighs, legs, thorax, and lastly the arms and hands. These symptoms are attended with a small, quick, and contracted pulse, great thirst, and the immediate rejection of whatever is taken into the stomach. "As the disease proceeds," says Dr. Copland, who witnessed its progress in an intertropical climate, and who experienced it in his own person, "the pulse becomes weaker and smaller; the spasms more general; the purging constant and painful, generally with tenesmus; the vomitings are renewed upon the ingestion of substances into the stomach; and the powers of life rapidly fail. During this time the fluids evacuated from the stomach and bowels present no appearance of bile, although occasionally bile is seen in the evacuations to a small extent. In the course of a few hours the features shrink, the hands and feet become cold and clammy; the exacerbation of the spasms forces out a cold clammy sweat on the face and breast; the pulse is extremely small and weak, or nearly disappears. In a case which came before me in Africa, in 1816, the pulse could scarcely be felt four hours from the attack; and the contents of the stomach are now, in the more dangerous cases, thrown off without any effort of retching. Commonly during all this time the faecal matters and the biliary secretions are retained, apparently owing to the extension of the spasms from the duodenum to the common biliary duct, and to spastic constrictions of parts of the colon; the epigastrium and hypochondria being sore, tense, and tumid. When the disease is treated with decision, the vomitings cease; free evacuations with a discharge of bile take place, and the patient soon recovers. But if neglected, or improperly managed, the powers of life fail rapidly; the eyes sink, and are surrounded with a livid circle; the countenance assumes a remarkably anxious cast, or is pale, wan, and shrunk; and the spasms extend to the very fingers. The breathing now becomes extremely laborious; the patient is restless, and at last is carried off, sometimes in the space of ten or twelve hours."

The pathological state constituting the disease seems to consist of irritation of the mucous surface of the digestive tube, commencing in the duodenum and extending in each direction to the stomach, small

intestines, and along the common duct to the gall-bladder and liver, with increased action of the muscular coats of these viscera and determination of the circulating fluid to them. This irritation or morbid excitement, owing to the connexion of the organic nerves supplying those parts, is propagated to the spinal nerves, by which the muscles of the abdomen and extremities are affected by painful and violent contractions; and it is chiefly owing to the exhaustion of the vital manifestations of the organic system of nerves, and to the frequent and profuse discharges, that a fatal issue takes place: the circulating organs, which are actuated by this system, being in consequence incapable of performing their functions.

In regard to the treatment, Sydenham recommends in the early part of the attack the promotion of the discharge of the offending matter by means of diluents, such as weak broths and soups; and since his time this practice has been very generally followed. When the discharge has continued some time opium is indispensable, which is best given in the form of pill, in doses of from one to three grains, repeated at short intervals. The muriate of morphia, in doses of from half a grain to two grains, is also an excellent remedy. In some cases the opium should be combined with calomel; and in the intense forms of this disease, common in warm climates, twenty grains of calomel combined with opium, repeated once or twice after an interval of from three to six hours, is found by experience to be the most effectual remedy. Under such circumstances these large and repeated doses of calomel do not salivate, partly because the whole of the calomel is never retained, and partly because the system is not in a condition favourable for the absorption of what does remain in the stomach.

The malady, new to this climate, which has spread to so many different nations of the globe, and which has swept away so many of its inhabitants, commonly known under the name of *pestilential*, or *Asiatic cholera*, is a different disease from that here treated of, and is noticed under the article PESTILENCE.

(For a minute account of the symptoms, and for the details of the treatment of bilious and spasmodic cholera, see Sydenham's works; Dr. James Johnson *On Diseases of Intertropical Climates*; Dr. Chisholm *On Diseases of Tropical Climates*; and Dr. Copland's *Dict. of Pract. Med.*)

CHOLESTERIC ACID ($C_{10}H_{10}O_{10}$?), one of the final products of the oxidation of either of the bile constituents with nitric acid. It is most conveniently obtained by saturating the mother-liquor, from the preparation of cholidanic acid, with ammonia, precipitating with nitrate of silver, and re-dissolving the precipitate in boiling water. On cooling, crystalline scales of *cholesterate of silver* separate, from which the acid may be isolated by suspending them in water, decomposing with sulphuretted hydrogen, filtering, and evaporating the solution to dryness.

Cholesteric acid is a yellowish, solid substance resembling cherry-tree gum. Its taste is sour and bitter. It is very soluble in water, alcohol, and acids. It forms soluble non-crystalline salts with the alkalies.

CHOLESTERILIN ($C_{52}H_{104}$) is obtained in three isomeric modifications by the action of concentrated sulphuric acid on cholesterol: *a* has an earthy appearance; *b* occurs in spangles; *c* is resinous and non-crystalline. They all yield cholesteric acid by oxidation with nitric acid.

CHOLESTERIN ($C_{52}H_{104}O_2 + 2 \text{ Aq.}$). This substance is a constant constituent of bile, though in very small quantity. It is also found in the blood, the brain, and in the yolk of egg. It frequently accumulates in the gall-bladder, forming what are called *gall-stones*; and it is from this variety of calculus that it is most easily prepared. Powdered and boiled with alcohol, the cholesterolin dissolves, and crystallises out on cooling. It is obtained quite pure by one or two re-crystallisations.

Cholesterolin is insoluble in water, slightly soluble in cold alcohol, very much so in boiling alcohol, ether, or wood-spirit. It fuses at about 280° Fahr. into a colourless liquid, that again becomes crystalline on cooling. Heated to near the boiling point of mercury, it volatilises without decomposition, forming a snowy-white sublimate. In the open air it burns with a smoky flame. The alkalies do not act upon it. Strong acids convert it into *cholesterilin* or *cholesteron*.

CHOLESTERON ($C_{52}H_{102}$), a solid hydrocarbon, somewhat similar to cholesterolin. It is derived from cholesterolin by the action of concentrated phosphoric acid. It crystallises in beautiful prisms or silky needles. Cholesteron and cholesterolin have the same chemical composition, containing the elements of cholesterolin less two equivalents of water.

CHOLESTROPHANE. [CAFFEINE.]

CHO'LIAMBIC, the name of a kind of verse employed by Greek and occasionally by Latin writers (*e.g.*, Martial). It consisted of six feet, and was regulated by the same general laws as the iambic verse of tragedy. In two or three points it differed considerably: the fifth foot was properly and generally an iambus, though a few instances are found of a spondee in its place: the sixth foot was always a spondee or trochee. From this circumstance the name

Choliambus (*χολιαμβός*) is derived, which means lame iambus; the metre limps, as it were, in the sixth foot. Anapæsts appear in the first foot, but in no other. Hipponax was one of the earliest writers in choliambic verse, and has therefore been called the inventor of it. The fragments of his poetry have been collected by Prof. Welcker. Simonides and Callimachus also wrote in this metre, and a few specimens from the latter poet remain. The age succeeding the death of Alexander contained many choliambic writers, who employed the same antiquated dialect that they found in the compositions of Hipponax and others. The fable-writer, Babrius [*BABRIUS*, *BIOG. DIV.*], who lived a little before the Augustan age, revived the choliambic poetry, and influenced probably by preceding poets, who had adopted the same metre, he appears not to have considered himself bound by the custom of his own age in the choice of words. (*'Philological Museum,'* vol. i.)

CHOLIC ACID ($C_{52}H_{43}NO_{12}$), (*Glycocholic acid; Glycocholalic acid*). Cholate of soda forms the principal portion of ox-bile. The cholic acid may be isolated and separated from the other biliary matters in the following manner: Bile is evaporated to dryness, and dried at a temperature of 250° Fahr. The residue is digested in cold absolute alcohol, the solution filtered, and ether added, which causes the separation of a brown resin, after which crystalline tufts are gradually deposited. These must be washed with absolute alcohol containing 10 per cent. of ether, dried *in vacuo*, redissolved in water, and dilute sulphuric acid added. The solution slowly deposits crystals of cholic acid, which may be further purified by another crystallisation from water.

Cholic acid forms white acicular crystals; they are slightly soluble in cold water, rather more so in boiling water. The solution has at once a bitter and a sweet taste, and an acid action on litmus paper. This acid is soluble in alcohol, less so in ether.

When treated with alkalies, cholic acid is converted into cholalic acid and *glycocin* (sugar of gelatin):

Boiled with sulphuric or hydrochloric acids, cholic acid yields, first, *cholonolic acid*; then, *glycocin* and *choloidic acid*; and finally, *dyslysin*.

Cholic acid combines with bases to form salts, some of which are crystalline. With sugar and sulphuric acid it gives a purple colouration.

CHOLÖIDANIC ACID ($C_{32}H_{24}O_{14}$), one of the products obtained by oxidising bile with nitric acid. It is most advantageously prepared by boiling choloidic acid in a retort with moderately strong nitric acid till no more red fumes are evolved. On cooling, a mass of crystals of cholöidanic acid separate out, which may be purified by pressure to remove excess of nitric acid, and by recrystallisation from boiling water. They present the appearance of asbestos, are almost insoluble in cold water, slightly so in hot water, and very soluble in alcohol.

Cholöidanic acid unites with bases, but the salts are with difficulty obtained in a pure state.

CHOLÖIDIC ACID ($C_{48}H_{35}O_8$). Formed by boiling cholic acid, choleic acid, or cholalic acid, with hydrochloric acid for three or four hours. On the cooling of the solution, it separates out as a solid mass, which may be purified by washing with water, solution in alcohol, and evaporating to dryness.

Cholöidic acid is a white solid, insoluble in water, soluble in alcohol, and slightly so in ether.

It decomposes carbonates with effervescence, but the salts which it forms are uncrystallisable.

CHOLONIC ACID ($C_{52}H_{41}NO_{10}$), the body that is first formed on boiling cholic acid with strong hydrochloric or sulphuric acids:

It separates out in oily drops that solidify on cooling. It may be purified by treating with caustic baryta, decomposing the resulting salt with hydrochloric acid, and crystallising from alcohol. It forms brilliant needles.

Cholonic acid forms soluble salts with the alkalies. The soda compound is crystalline. With the alkaline earths it forms insoluble combinations.

The relation which the above-mentioned acids bear to each other, and to bile, will be at once seen by a glance at the following table:—

	Products by Alkalies.	Products by Acids.	Products by Oxidation.
Bile from the ox.	Choleic acid.	Cholalic acid.	Cholacrol.
	Taurin.	Choloidic acid.	Nitrocholic acid.
		Dyslysin.	Choloidanic acid.
			Cholesteric acid.
Cholic acid.	Cholalic acid.	Cholonic acid.	Cholacrol.
	Glycocin.	Choloidic.	Nitrocholic acid.
		Dyslysin.	Choloidanic acid.
			Cholesteric acid.
Cholesterin.		Cholesterilin.	
		Cholesteron.	Cholesteric acid.

These acids are principally combined with soda, forming a species of soap.

The reactions with sugar and sulphuric acid, mentioned under **CHOLEIC** and **CHOLIC ACIDS**, has been taken advantage of by Pettenkofer as a means of testing for the presence of bile in organic matters. It is best applied as follows: An extract, obtained by digesting the substance in alcohol and evaporating to dryness, is dissolved in a little water, a few grains of sugar added, and pure sulphuric acid cautiously poured in. A red colour ensues, changing to purple and violet if bile is present. [See also **BILE**, *NAT. HIST. DIV.*]

CHONDRIN. A kind of gelatine from which it differs in being coagulated by vegetable acids. It is obtained by boiling the cornea of the eye with water.

CHORA'GUS, the name of a public officer at Athens. Each phyle, or tribe, had a choragus (*χοραγός*), who was obliged to provide a chorus to perform at the representations in the theatres, and at many religious solemnities. The office was probably rotatory, though none but rich persons able to bear the expenditure without inconvenience could be forced to take it. (Fred. Aug. Wolf, *'Prolegomena in Demosth. Orat. Leptin.'* p. lxxxvii.) The choragus had entire charge of the whole choral apparatus: he paid for the dresses and the crowns, and all other decorations. He also provided and paid a teacher (*χοροδιδάσκαλος*, chorus-teacher), who instructed and trained the choristers in the arts and graces of their profession. Every expense of whatever kind attendant on the equipment of a chorus, either in the theatre or in any other exhibition, was discharged by the choragus. The tribes vied with one another in the splendour of their exhibitions, and especially in the sumptuousness of the choral ornaments: sometimes the expenses incurred by the state were so heavy, that both the treasury and the resources of individuals were exhausted. (See also *'Xen. Hipparch.'* i. 26.) In some cases the choragus seems to have led the chorus in person, as well as to have defrayed the expenses; and once a choragus acted as flute-player at Sparta. (Müller, *'Dorians,'* vol. ii., p. 341.) The term choragus included sometimes the gymnasiarch and the hestiator. (Fred. Aug. Wolf, in *'Demosth. Leptin. Orat. Comment.'* 16, 24.) The former of these had charge of the athletic exercises of the youth; and the latter was obliged to give a banquet to his tribe on occasion of any great holiday or festival: these offices were similar in kind to that of the choragus, which probably from being the most expensive and important of the three, stands frequently for the whole. The choragus is not to be confounded with the choropoios (*χοροποιός*), who was general chorus-manager to all the tribes. (Xenoph. *'Ages,'* ii. 17; Müller, *'Dorians,'* vol. ii., p. 341, n.) Some age appears to have been fixed below which it was not competent to a man to be made choragus: a choragus of boys could not be under forty years of age; the age required in other cases is not known. A resident alien or metic (*μέτοικος*) could not hold the office. Demosthenes was on one occasion a volunteer choragus, and was grievously insulted during his term of office by Meidias. (Demosth. *'Against Meidias.'*) A tripod was the common prize of the successful choragus, who occasionally erected a small building on which he placed the prize. Such is the beautiful choragic monument of Lysicrates (erected about 334 B.C.) at Athens, vulgarly called the Lantern of Demosthenes. These monuments were erected in the vicinity of the theatre, or in the street on the eastern side of the Acropolis, which led from the Prytaneum to the sacred enclosure of Dionysus—hence called the "street of the tripods."

CHORD (in mathematics), a straight line drawn from one point to another of a curve. [*ARC*]. The term chord was also used in trigonometry, with sine, cosine, &c., to denote the chord of a circle, in which case it was also called the chord of the subtending angle. But this term, not being wanted, has not passed into pure algebra with sine, cosine, &c. [*CIRCLE*], so that when used, it must be considered as retaining its primitive sense, namely, that of a straight line, not an abstract number expressing the ratio of a straight line to the radius. To find the chord of a given angle, multiply the diameter by the sine of half the angle. Thus the angle being $23^{\circ} 20'$, and its half $11^{\circ} 40'$, take the sine of the half, which is .2022176. If the diameter be 100 feet, then the chord of $23^{\circ} 20'$ is 20.22176 , or $20\frac{1}{4}$ feet nearly.

To find the chord of a given arc, find the angle subtending the given arc [*ANGLE*], and proceed as before. The following Table of Chords, to every degree up to 180° , will frequently be useful in rough calculations. The diameter is throughout 10,000, to avoid decimals.

TABLE OF CHORDS (DIAMETER 10,000).

74	6018	109	8141	144	9511	179	9999
75	6088	110	8192	145	9537	180	10000

To use this Table, roughly, take out the chord of the nearest degree, multiply by the diameter, and divide by 10,000. Thus for a diameter of 2 feet, and an angle of 10° (supposing decimals are to be avoided), take out 872 opposite to 10° , and multiply by 2, giving 1744, which in inches is 20,928, which divided by 10,000, gives 2 inches, and 1-10th of an inch, very nearly.

An easy method of verifying the preceding table (if a doubt arise in any case) is contained in the following relations, which apply according as x is greater or less than 120° .

$$\begin{aligned} \text{ch. of } (x - 120^\circ) + \text{ch. } (240^\circ - x) &= \text{ch. } x. \\ \text{ch. of } (120^\circ + x) - \text{ch. } (120^\circ - x) &= \text{ch. } x. \\ \text{ch. of } (180^\circ + x) &= \text{ch. of } (180^\circ - x) \end{aligned}$$

For instance, the chord of 130° is made up of those of 10° and 110° ; the chord of 50° is the difference between those of 170° and 70° . These will be true within a unit, if the Table be correct.

CHORD, in music, is the harmonious combination of three or more musical sounds.

To account for the origin of chords, many theories have been proposed, the principal whereof are, that of Rameau—which D'Alembert endeavoured to elucidate, and Marpurge partly built his system on—and those of Tartini and Kirnberger. These theories, in the main, all arise out of, or finally resolve into, the natural harmonics of a distended string. But it will be proper here to state that Sir John Herschel, in his treatise on Sound, contained in the 'Encyclopædia Metropolitana,' declares "the insufficiency of any attempt to establish the whole theory of harmony and music on the aliquot subdivision of a musical string." Nevertheless, the facts that result from the simple division of a stretched string agreeing with the natural harmonic divisions of a sonorous tube—the French horn, for instance—and which cannot be disputed—are sufficient to prove that the foundation of what is properly called harmony was not arbitrarily laid. These facts may thus be briefly stated: the whole string gives, of course, the gravest, or generating, sound; four-fifths of the string give the major 3rd; two-thirds give the perfect 5th; and one-half gives the octave. Thus is produced the perfect or common chord, or triad, which, together with the chord of the seventh, is the source of all other real chords.

The Perfect Chord consists of any given note, together with a major 3rd and perfect 5th, which sounds may be represented by the letters C, E, G, or by the syllables *do*, *mi*, *sol*. It has two inversions, or derivatives: the first is made by taking the E (*mi*) as the base, producing the chord of the *sixth*; the second, by taking the G (*sol*) as the base, producing the chord of the *sixth* and *fourth*. Example:—

This chord is denominated the Perfect Minor Chord when its 3rd is flattened; and, so altered, its inversions are affected accordingly. Example:—

The chord of the seventh—called the Dominant Seventh—is formed by adding to the perfect chord a minor 7th, and consists of a given note, together with a major 3rd, a perfect 5th, and a minor 7th. It may be represented by the letters G, B, D, F, or by the syllables *sol*, *si*, *re*, *fa*. This has three inversions: the first is made by taking the B (*si*) as the base, producing the chord of the *sixth* and *fifth*; the second, by taking the D (*re*) as the base, producing the chord of the *fourth* and *third*; the third, by taking F (*fa*) as the base, producing the chord of the *fourth* and *second*. Example:—

The Perfect Chord, and its inversions, are called consonant chords all other chords, and their inversions, are called dissonant chords.

The chord of the Imperfect, or Minor, Seventh, consists of a given note, a minor 3rd, an imperfect 5th, and a 7th. Example:—

The chord of the Diminished Seventh—sometimes called the Equivocal Chord—consists of a given note, its minor 3rd, imperfect 5th, and diminished 7th. Example:—

The chord of the Dominant Ninth consists of a given note, its major 3rd, 5th, 7th and 9th. Example:—

This chord has three inversions, though they are not in very common use. M. Catel gives them in the following manner:

But by far the most elegant form which the chord of the Ninth and Seventh assumes is a retardation of the 8th and 6th. Example:—

The Dominant Minor Ninth consists of the same sounds as the Dominant Ninth, but the 9th is flat. Example:—

This has three inversions, which also we extract from M. Catel's treatise:—

We have seen, that by adding to the Perfect Chord a 3rd above its 5th, the chord of the Seventh is formed: by the further addition of thirds, theorists form other chords, sometimes called *chords by supposition*. These are, the chord of the Ninth, of the Eleventh, and of the Thirteenth. The last three chords, as well as others presently to be mentioned, are merely chords of retardation: or, in other words, the dissonant notes in them are but appoggiaturas.

The chord of the Ninth consists of a given note, its 3rd, 5th, and 9th, the discord retarding the 8th. Example:—

The chord of the Eleventh (more commonly called the chord of the Sharp Seventh), consists of a given note, its 4th (or 11th), 5th, major 7th, and 9th. It is a retardation of the perfect chord, the 9th and 7th retarding the 8th, and the 4th retarding the 3rd, of the perfect chord. Example:—

This chord is almost invariably figured by a ♯, accompanied by a 5th, 4th, and 2nd; but as the discord of the 2nd is always resolved in the base, it cannot, under such name, form a part of the chord of the eleventh.

The chord of the Thirteenth consists of a given note, its 4th, 6th (or 13th), major 7th, and 9th. This is a retardation of the perfect minor chord, the 4th and 6th retarding the 3rd and 5th, the 7th and 9th retarding the 8th. Example:

The chord of the Fifth and Second consists of a given note, its 2nd and 5th. Example:

Albrechtberger considers this chord as one form of the chord of the Eleventh, but the discord being resolved in the base proves it to be a 2nd, not a 9th. It is, in fact, the Sixth retarded by the base.

The chord of the Fifth and Fourth consists of a given note, its 4th and 5th, and retards the perfect chord, the 4th retarding the 3rd. Example:—

The chord of the Ninth and Fourth consists of a given note, its 4th, 5th, and 9th. This also retards the perfect chord, the 4th and 9th retarding the 3rd and 8th. Example:—

We will only add that the nomenclature of chords stands much in need of correction; but, unhappily, it is not the only branch of the theory of music that is confused and perplexing, from want of logical accuracy and lucid arrangement.

CHOREA (remotely from the Greek *χορεία*, and immediately from the Latin *chorea*, a dance with singing—Chorea Sancti Viti—Saint Vitus's Dance), a disease affecting with irregular movements the muscles of voluntary motion, these muscles being no longer under the command of the will, and the power both of walking and of using the arms and hands being impaired. The chief external manifestations of this disease are in the muscles of voluntary motion; but its real seat is in certain internal organs, frequently in those which belong to the apparatus of digestion. If the history of any case of chorea be carefully examined from the commencement, it will be found that the more manifest disorder has been preceded by deranged appetite, which is sometimes voracious, and at other times altogether lost; by constipated bowels, and by imperfect digestion. There is at the same time a remarkable failure of the general physical strength. The derangement in these organic functions is always accompanied with a greater or less degree of mental disorder. The mind is irritable and fretful, and oftentimes reserved, gloomy, and desirous of solitude. After this state of physical and mental disorder has continued some time, and the languor, lassitude, and general weakness of the system have proportionally increased, there come on irregular and involuntary twitchings of the muscles, particularly the muscles of the face, which at first are thought by the friends of the patient to be merely the effect of imitation. But these convulsive motions progressively increase, until the muscles of the extremities, face, lower jaw, head, and trunk, all become agitated with violent and irregular movements. In this case the patient is incapable of walking steadily, his gait is jumping or starting; sometimes he is altogether unable to walk, and seems palsied, while he is equally unable to perform the ordinary motions with the affected arm.

A century and a half ago Sydenham gave the following graphic and correct description of the convulsive motions characteristic of this disease when fully formed. "First it shows itself by a lameness or rather instability of one of the legs, which the patient drags after him like a fool. Afterwards it appears in the hand of the same side, which he that is affected with the disease can by no means keep in the same posture for one moment; if it be brought to the breast or any other part, it will be distorted to another position or place by a convulsion, let the patient do what he can. If a cup of drink be put into his hand he represents a thousand gestures, like jugglers, before he brings it to his mouth; for whereas he cannot carry it to his mouth in a right line, his hand being drawn hither and thither by the convulsion; he turns it often about for some time, till at length, happily reaching his lips, he flings it suddenly into his mouth, and drinks it greedily, as if designing only to make sport."

As the disease advances the power of distinct articulation is lost: even the deglutition becomes difficult, in some cases, to such a degree that fluids are forcibly thrown up from the pharynx in attempts at swallowing them; the eyes lose their lustre; the complexion becomes pallid and muddy; the expression of the countenance languid and vacant; and in the severest cases the mouth is variously twisted and the saliva drivels from it; the tongue is protruded irregularly and spasmodically; the eyes are distorted and rolled in various directions, and the sight is occasionally defective. The muscles meantime become soft and flaccid; emaciation takes place; the pulse is weak, but not much quickened; the urine is pale and copious, and the bowels are always constipated.

The mind, irritable from the commencement, is now harassed by painful images and incongruous ideas, which every effort is made to conceal, and various desires and emotions are produced, sometimes without apparent cause. This disordered condition of the mind, when the disease is severe and long-continued, ultimately terminates in a state of fatuity, of which the pallid, listless, and vacant countenance is the external sign and expression.

This disease is common to both sexes, but it is much more frequent in the female than in the male, in the proportion of about three of the former to one of the latter. It seldom attacks before the 8th, nor after the 15th or 16th, year of age, although no period of life is wholly exempt from it. The different muscles that are affected, and the different degrees in which they are agitated by the irregular motions, give an endless diversity to the external appearance of different cases; for the convulsive motions are sometimes slight, at other times severe, sometimes partial, at other times general; but most commonly they are partial, and sometimes they are strictly confined to one side. The duration of the disease may vary from a few weeks to many months.

Chorea is often associated with other affections more or less closely allied to it in nature, and alternates with them. In the female it is often observed in connexion with chlorosis, with the suppression of the catamenial discharge, and with hysteria, and in the male with rheumatism, paralysis, and dropsy. Occasionally it terminates in epilepsy, paralysis, dropsy, particularly hydrocephalus, and, as has been stated, complete idiocy. Cases are on record in which it has terminated in violent convulsions, and inflammation of the brain, followed by coma and death. It often accompanies disease of the heart.

Such being the occasional issue, the disease ought in no case to be neglected or trifled with, especially when, as is invariably the case, the postponement of the proper treatment greatly increases the difficulty of the cure. In general, under proper management, the disease is removed without difficulty, and the return to health is commonly

complete, although this is one of the affections which is peculiarly subject to relapse. It is not at all uncommon for the patient, when apparently cured, to be attacked several times in succession either with the same disease or with some one of the affections into which it has been stated to have so great a tendency to lapse. Still however those relapses are curable by persevering in the proper treatment, and it is remarkable that even when paralysis and idiocy appear to be fully established they yield far more readily to appropriate remedies than when those affections have been induced by a primary affection of the brain.

Chorea arises in widely different states of the system, and is produced by different causes, and therefore in different cases requires a different treatment. In many cases it arises from an accumulation of irritating matter in the alimentary canal, which must be removed by a course of purgative medicines. The choice of the purgative and the duration of the course must depend on the state of the system in each particular case; but in general the purgative must be of an active nature, and the course decided and long continued. At the same time the strict regulation of the diet, both as to the quality and the quantity of the food, is indispensable. As this malady almost invariably occurs in an enfeebled state of the constitution, active exercise in fresh and pure air, and the administration of the preparations of iron are to be recommended.

When this affection is connected, as it occasionally is, with organic disease of the spinal cord or brain, it is of the last importance to the proper treatment of the case that this organic lesion should be discriminated, and that the remedies proper to it should be promptly applied. From what has been stated it will appear that this is one of the diseases which should engage the anxious attention of parents, teachers, and all who have the charge of young persons of either sex. Not only the health or disease of puberty and adolescence, but the health or disease, physical and mental, of mature age, may depend on their prompt attention to, or neglect of, the very first symptoms of this malady.

CHORUS, among the Greeks, was a number of persons, male or female, who sang melodies accompanied with dancing. The chorus appears to have been of Doric origin, and the Doric dialect continued to be chiefly used, even in the choral songs of Attic tragedies. (Müller, 'Dorians,' vol. ii, p. 381.) Originally the choral performance was a separate exhibition, and was of a religious character: hymns were chanted in honour of Dionysus and other gods. Afterwards an actor was added by Thespis, who first introduced the dialogue; other changes were made by his successors, especially Phrynichus, till a second actor was added by Æschylus, who embodied the chorus in the constitution of the Greek drama, as a part and only a part of the representation. Many explanations of the object of the chorus have been offered by different writers. It would certainly give a very imperfect idea of its office, to say that it was only retained in order to give the other actors breathing-time, and to prevent a break in the performance. The chorus may be regarded rather as the representation of the aggregate body of spectators: the chorus generally gave utterance to those emotions of pleasure or sorrow which the audience might be supposed to feel. They sometimes took upon themselves to give instruction or to administer reproof.

The tragic chorus consisted at first of fifty, afterwards of fifteen persons; the comic chorus consisted of twenty-four. According to Julius Pollux ('Onomast.' iv. 15), the number of the tragic chorus was abridged after the performance of the Eumenides of Æschylus: the alarm caused by fifty of these ladies was too great. The chorus entered into the orchestra, and remained there performing their evolutions, and observing the thymele or altar, which was in the middle of the orchestra, as the centre of their movements. As they sang they moved in a dance, suited to the subject of their song, and modulated by the accompanying music; sometimes the movements of the dance were so appropriate as to convey to the spectators the full meaning of the chorus, independently of the words of the song. The perfection to which the Greeks carried their skill in affecting an audience by the harmonious union of dancing and music forms one of the main differences between the ancient and modern theatre. The songs of the chorus consisted of three parts, the strophe (or *turning*), the antistrophe (*opposite turning*), and the epode (*after-song*): during the first they turned from right to left, during the second from left to right, and during the third they stood still in front of the spectators. When they sang, they all sang; when they took part in the dialogue, one only, the coryphæus or leader of the chorus, spoke, from the top of the thymele; and hence in addresses to the chorus there is a constant change of number—*thou* and *ye*. (Schlegel, 'Theatre of the Greeks.') Frequently they divided into two sets, who, by means of their two leaders, carried on a separate dialogue, which generally revealed their sentiments on the progress of the plot, their fears, anxieties, and hopes. They also chanted hymns of supplication or thanksgiving to the gods.

The choruses at Athens did not perform exclusively in the theatre, but on many occasions when there was no scenic representation at all. At the Panathenæa and the Thargelia, and at the Gymnopædia of Sparta, choruses of men and boys sang. All choruses at Athens were provided, equipped, and instructed, by persons appointed by the several tribes. [CHORAGUS.]

CHORUS, in music, a composition sometimes in two or three, but

generally in four parts, sung by many voices, accompanied by the whole band when performed in an orchestra or on the stage, but by the organ alone when sung in a choir. The chorus of the oratorio and opera has full instrumental accompaniments, but that of our cathedral services and anthems is written with only an organ accompaniment.

The term CHORUS is also applied in an aggregate sense to the whole body of singers performing the chorus.

A DOUBLE CHORUS is in eight vocal parts, and sung by two choirs. Many of Handel's choruses in 'Israel in Egypt,' in 'Solomon,' and in 'Deborah,' are of this kind.

CHOSE IN ACTION is a technical term in the law of England, denoting that kind of property of which the owner is not in the actual possession or occupation, though he has a legal right to obtain the possession. As this right can only, in general, be enforced by action, the property, whatever its nature, is termed a thing (*res*), or *chose in action*, in contradistinction from a thing or property in *possession*. Thus if I buy a quarter of wheat out of a large quantity, my interest in the wheat is a property to which I have a right. If the seller, in breach of his engagement, refuses to deliver it, I can only assert my right through the medium of an action or suit. As long as I have only the right of enforcing the delivery of the wheat, or recovering an equivalent in damages, and do not obtain the actual possession, my property in the wheat is a chose in action, being, as a property, a thing rather in *potentia* than in *esse*. In like manner money due upon a bond or a bill of exchange is a chose in action; and also the right to compensation for damage sustained by means of the breach of any kind of contract.

The policy of the English law, in discouraging all contracts tending to promote litigation, introduced a rule that property in action merely, and not in possession, could not be assigned or transferred to any third person. This rule has in modern times received considerable modification. In the familiar instance of bills of exchange, drafts on bankers (which are in law bills of exchange), and promissory notes (all which are strictly choses in action), an indorsement not only transfers to the indorsee the absolute right to the sum to be recovered, but also enables him to sue in the common law-courts upon the bill or note in his own name. Courts of equity in other cases protect assignments of choses in action; but in these cases the assignee must sue in the name of the original contractor, whom the law, regarding the assignment, which it does not sanction, as a nullity, treats as the party still entitled, if the assignee proceeds at law. (Blackstone's 'Comm.,' vol. i. pp. 403, 452.)

CHRISM, sometimes written CRISOME, or CHRISTOM, in its strict interpretation means "unction," from the Greek *χρίσμα* (*chrisma*), ointment; but is more generally received as the name for oil consecrated by the bishop, and used in the Romish and Greek churches in the administration of baptism, confirmation, ordination, and extreme unction: and is, or used to be, prepared on Holy Thursday with much ceremony. Ducange ('Glossar. ad Script. Med. et Infimæ Latinitatis,' edit. Francof. ad Mœn., 1681, tom. i., col. 973) says there are two kinds of chrism, the one prepared of oil and balsam, used in baptism, confirmation, and ordination, the other of oil alone, consecrated by the bishop, anciently used for the catechumens, and still used in extreme unction. (See also Durand's 'Rationale Divinorum Officiorum,' lib. vi., cap. 74, 84.) The word *crisome* is also found applied to the cloth which was laid over a child's face when baptised, to prevent the unguent from running off. (See the 'Liturgy' compiled in the 2nd year of Edward VI.) Children likewise who died in the first month were called Chrisomes in the old bills of mortality; and the white cloth was used as a shroud. Mrs. Quickly says of Falstaff ('Henry V.' ii. 3), "A made a finer end, and went away, an it had been any christom child."

CHRIST'S HOSPITAL, London. The hospitals of Christ, Bride-well, and Saint Thomas the Apostle, were founded by the same charter of king Edward VI., dated 26th of June, 1553; for the support of which he granted to the mayor and commonalty, and to the citizens of London, numerous possessions within the city of London, and the counties of Middlesex, Essex, Hertford, Buckingham, Cambridge, Kent, Derby, and York. Christ's Hospital was established upon the site of the house of Mendicants or Grey Friars, in Newgate Street, about five years after the king's grant; when about four hundred orphans were admitted, and clothed in russet, which was soon afterwards changed for the dress which they now wear, namely, a blue coat or tunic, reaching to the feet, with yellow stockings, and a round bonnet or cap. The institution has little or no income under the charter. It is apprehended that the estates which were given under it to the city of London were afterwards apportioned to the royal hospitals as the citizens thought fit. All its other estates can be traced to legacies and donations of different periods. At the suggestion of Sir Robert Clayton, then lord mayor, and a considerable benefactor, king Charles II., in 1676, granted a second charter, allowing 1000*l.* a year, for seven years, to establish a mathematical school for forty boys, and an annuity of 370*l.* 10*s.*, payable at the Exchequer, for the especial purpose of educating and placing out yearly ten boys in the sea-service. These boys remain in the hospital until they are thus provided for.

The greater part of this hospital was involved in the destructive fire of London in 1666; but by the zeal and liberality of the corporation of London, aided by donations, loans, and the operation of the revenues of the hospital, it soon revived, and was rebuilt under the able direction of Sir Christopher Wren. The buildings, however, having, to a certain

extent, fallen into decay, from their antiquity, and the funds of the charity being unequal to their entire restoration upon a plan of suitable uniformity and convenience, it was resolved, at a general court of the governors, on the 28th of January, 1803, to open a subscription for that purpose, when the corporation of London gave 1000*l.*; several of the city companies followed the example, and the donations for this purpose up to 1833, chiefly of individuals, amounted to 38,676*l.* The great work of rebuilding was commenced in 1825, under the direction of Mr. Shaw, by whom the magnificent hall, only second in size to that of Westminster, the grammar school, some of the dormitories, and the infirmary, were constructed. Since then other improvements have been made. In 1858 the site of the old Giltspur Street Compter was acquired, and formed into a play-ground; and in 1859 the entrances from Newgate Street were rendered ornamental.

The managing governors of the hospital are the mayor and commonalty of the city of London, represented by the lord mayor, aldermen, and twelve common council-men, who are chosen by the rest of the common council out of their own body, according to an Act of Parliament obtained in 1782, to settle the disputes between the city of London and the hospital. Besides the corporation, noblemen and gentlemen of all ranks are governors, who become benefactors to the amount of 400*l.* The number of governors of this kind is not limited. The right of presentation is vested in the governors in rotation, and in some of the officers by virtue of their offices. The children presented must be not less than seven nor more than ten years of age, and they come out at fifteen, except those boys who become Grecians, when they remain till they are eighteen or nineteen. Of these Grecians, there used to be six, increased in 1857 to eight, who are sent, with considerable endowments arising from the gift of the hospital itself, and from various scholarships founded by individuals, to the universities of Oxford and Cambridge.

In 1683 the governors erected a handsome building in the town of Hertford, for both boys and girls. The girls permanently remain here. All the boys are also sent to Hertford, and here they are nursed and instructed until they are rendered capable of receiving the more advanced education of the foundation in London. The establishment at Hertford, when full, contains upwards of 400.

The accommodation in the two establishments in London and at Hertford is for about 1200 boys, and at Hertford for 70 girls.

In London there are classical masters, writing masters, mathematical, drawing, and singing masters, with masters for French and German; and in most of the departments there are also assistant-masters or ushers. It should be observed, that the boys' school is essentially classical; Latin and Greek are taught to all as the fundamental principles of their education. Mathematics are also essential to King Charles's foundation, and to those students who aspire to be deputy Grecians or Grecians; but all may be taught if they apply. Drawing and the living foreign languages are modern improvements. The girls are only taught the common branches of education, and are instructed in matters of domestic economy, so as to fit them for household service. At Hertford there are a classical master, writing master, two ushers, and two mistresses to the girls' school; besides nurses, &c., at each.

The gross income of the charity averages about 50,000*l.* The expenses are kept somewhat below the income, and these accumulations allow for occasional extensions, as in the addition of two Grecians. The governors enjoy the patronage of several ecclesiastical benefices, most of them in the counties of Essex and Surrey.

CHRISTIAN KNOWLEDGE SOCIETY FOR THE PROMOTION OF, is the oldest society in the kingdom established for the education and religious instruction of the poor. It is an incorporated society, and is supported by the members of the Church of England. Its founder may be considered to have been the Rev. Dr. Thomas Bray, who, with four others, held their first meeting on March 8, 1698-9, and it was incorporated in 1701. The chief objects pursued by Dr. Bray were the promotion of charity schools, the planting of the Episcopal Church in British colonies; the formation of lending libraries, and the furnishing of cheap books and depositories of books for poor clergymen and students for holy orders. With a vast development, these continue to be the objects to which the exertions of the society are directed. In the first year of its existence, industrial schools were projected, and parochial charity schools founded; there are now nearly 25,000 such schools, with nearly a million and a half of children taught in them. In 1701 the system of school inspection was instituted; and this was followed by the founding of training institutions for schoolmasters and schoolmistresses. The society continues to give assistance, chiefly by supplying books to schools founded for the gratuitous or cheap education of the poor on Church of England principles; and it was the instituter, and continues to be the supporter, of the annual assemblage of the charity children of the metropolis in the cathedral of St. Paul's.

In the colonies and dependencies of the British empire the expenditure of the society has been on a larger scale. It sent missionaries to India as early as 1749,—among them the celebrated Schwarz; it has promoted the establishment of all the colonial bishoprics, contributing upwards of 30,000*l.* towards their endowment; it has given above 90,000*l.* for building of colonial churches; and it has furnished between 40,000*l.* and 50,000*l.* to various colonial colleges and college-schools. But the chief field of the society's exertions has been the preparation and circulation of books and tracts; more especially of Bibles, Testa-

ments, and Prayer Books. We have already mentioned [BIBLE SOCIETIES] its labours in that department. These works are supplied to the public at an average annual loss to the society of about 14,000*l.* The yearly issue is about 135,000 Bibles, 70,000 New Testaments, and 345,000 Prayer Books. From the year 1733, when the society first began to report its annual issues, nearly nine million Bibles and New Testaments have been distributed, and nearly eleven million Prayer Books. For purposes of Christian education, it also publishes largely both in the form of cheap tracts and of works possessing scientific and literary excellence and beauty of appearance. By these, though comparatively cheap, the society does not profess to lose, but the total issue is enormous. The annual average is about three millions and a half; and from 1733 to April, 1859, not less than one hundred and thirty-six millions of books and tracts have been sold.

The income of the society arises from subscriptions, donations, benefactions, and the sale of its books. Subscribers and donors have the privilege of purchasing the society's publications at a reduced rate. In the year ending April, 1859, the total receipts were 100,061*l.*, of which 61,848*l.* arose from the sale of works, and the remainder from the sources mentioned above. In the same year the expenditure was 100,062*l.*, of which 74,459*l.* were for the production of the various works sold, 6000*l.* were spent in various ways on the colonies, about 2000*l.* went for salaries and management, and the remainder in miscellaneous items. An East Indian missionary fund has been recently established, and is kept distinct by the society; but this has been included in the above statement.

CHRISTIANITY, that system of religion which has for its founder Jesus Christ.

The history of Christianity may be divided into three periods, of which the first embraces the life and ministry of Jesus Christ; the second comprehends the acts of the apostles after the death and resurrection of Christ, and the formation of the Christian church; the third period comprehends the history of the church from the termination of the labours of the apostles to the present day, and is a distinct subject from the history of the first two periods, so far as concerns the essential doctrines of Christianity.

The communities or churches founded by the apostles soon began to differ in various points of doctrine and discipline. From these differences arose a long series of violent disputes and animosities among the various religious parties or communities into which the whole body of Christians was divided. The frame of civil society also, in all the countries into which Christianity was gradually introduced, was necessarily affected by the new religion. Thus the history of the Christian church immediately subsequent to the cessation of the apostles' mission, and indeed we may say during the time of their mission, is inseparable from the history of all the several political societies among which Christianity was established. The history of Christianised Asia, Africa, and Europe, for several centuries, might with more propriety be called the history of the church in this or that country, than any thing else. The word church is here used in that proper and large sense which is pointed out at the end of the article CHURCH.

Viewing, however, the history of the church as a distinct subject, and paying no regard to the events of civil society, except so far as they are immediately and intimately connected with the church (the term here being used in a narrower sense), such a history is generally supposed to possess a sufficient unity of subject, as distinguished from civil history, to form a separate and distinct division of historical inquiry. Accordingly we have numerous histories of the church, whose professed object is to develop the progress of Christian doctrines, of the various opinions on matters of faith and discipline which have divided Christians, and of the various communities or associations into which Christians have been distributed. But these histories, in all ages, being mainly written by the clergy, are often not so much histories of the great body of Christians in this or that country, as of those whose immediate interests were often little identified with the interests of those whom it was their business to instruct. Such a contracted view of the history of Christianity, and of the history of the church in the several countries where Christianity is established, must always appear unsatisfactory to those who, considering the origin of the religion of Jesus Christ, its progress, and its development, as the great subject of the political drama of the civilised world for eighteen centuries, regard the history of the church or of a church, not as in any respect dissociated from civil history, but as a component part of it. Intimately blended with all the relations of life, with all the great events of political society, and now for at least fourteen centuries directing or influencing all the functions of government, and by turns assisting or retarding the progress of knowledge, according to the various forms in which it has been moulded for political purposes, a history of the church, distinct from the political history of the same nation and the same period, can have little value, except so far as it may be a good history of the clergy. Such a history of the church, however, has been often attempted by men neither deficient in industry nor learning; but the one-sided view which they have taken has never satisfied careful inquirers, and has only had the effect of forming in the minds of those who read much and think little, a certain confused notion of some essential difference between the history of the church and the history of those who, in various ages,

have composed that church. On the other hand, writers of what is called history in the usual acceptation of the term, often seem to consider the history of the church as hardly lying within their sphere. It is true that those great events in the history of the church which have changed the face of society are not and cannot be overlooked by such writers; but the influence of the slow and incessant working of the great principle of Christianity, which is intimately blended with all the social systems of all the countries where Christianity is established, and by its all-pervading power penetrates to their remotest and minutest members, and enters into all the recesses of domestic life, is rarely glanced at, and seldom, if ever, duly estimated by writers of history. The history of civilisation, which is the history of a continued progress, would appear to every reflecting person inseparable from the history of Christianity, or, in other words, of the Church, taking this word in its large and proper sense. The public acts of the clergy as a body receive a place among other public events in our annals and our histories; but as the real history of a people is generally sunk in the history of their rulers, so that of the true church is merged in the history of the clergy.

A history, then, called a history of *the* church, in the sense in which we believe all writers of general church history have understood the term, appears to be a division of history which ought either to be entitled a History of the Clergy and of their Acts and Opinions, or it ought so to be blended with general civil history as to render a separate name unnecessary.

Instead of attempting a history of the church in any sense, we have treated of the characteristic doctrines and discipline of the various bodies of Christians, whether properly called churches, or improperly so called, under their several heads. [BAPTISTS; CHURCH; CATHOLIC CHURCH, ROMAN, &c.]

Christianity is at present diffused over a large part of the world; but it can only be said to be established, either by the authority of the state, or by general consent, in the following countries. Christianity is established in all parts of Europe except the Ottoman dominions. In America, it is established in all those countries which are now under the dominion of descendants of Europeans, which are, in fact, the largest and best parts of the continent. In Africa, it exists in Abyssinia in a very corrupt state, and among the Copts of Egypt, who are now very inconsiderable in numbers. In Asia, the Christian religion is established in Armenia, but the number of Armenian Christians must not be estimated by the population of the country, for the merchants of this active and industrious people are found in many parts of Europe and Asia. In Syria, a branch of the Greek church still exists in the mountains of Libanus and the island of Cyprus; another in part of Syria and Diarbekr; and the Nestorians, who also belong to the Greek church, are found in Asiatic Turkey, about Mosul on the Tigris, in Persia, and also in some parts of India under the name of Christians of St. Thomas. In China and Japan Christianity at one time had made considerable progress, but in both was extinguished by a most unsparing persecution. In all the foreign dependencies of European powers, and especially those of the British empire, Christianity may be considered as established; though in many cases, as, for instance, in the British possessions in India, the number of Christians is small, when compared with the natives. But the zealous and persevering labours of European and American missionaries are now diffusing a knowledge of Christianity, and with it, of the useful arts of life, over countries hardly accessible to commercial enterprise; and it may safely be predicted that, by their efforts, and the spirit of colonisation which distinguishes some of the European nations, Christianity will rapidly spread itself over a much larger part of the habitable globe. The two other religions which occupy so large a portion of the earth's surface, Mohammedanism and Buddhism, are limited as to the sphere within which they can extend their doctrines, and it seems unlikely that they will pass the limits within which they are now confined. But Christianity being the religion of the most enterprising part of the human race, of those whose life consists in action more than in tranquillity and repose, is in a state of continual progress and diffusion; and it is probably to this difference between the temperament of most of the nations of Europe (a difference in some degree dependent on climate and local circumstances), and those of Asia and Africa, that Christianity still languishes among its comparatively few native professors in Asia and Africa, while the zeal and superior activity of the European race animate the missionaries of England and of the United States to preach the doctrines of Christianity in the very place of its birth, and to rival the old Catholic missionaries in zeal and courage. As the Apostles and the martyrs of the church testified the sincerity of their faith by their willingness to undergo every kind of suffering, and even death; so, in our own days, the apostles of Christianity, penetrating among the most uncivilised and savage tribes of the earth, have exhibited examples of courage, perseverance, and self-devotion unparalleled in the history of man.

In Africa, Christianity has hitherto made the least progress: and indeed wherever the Mohammedans have settled in that country, it has gradually decayed or disappeared. The Christian churches of the south coasts of the Mediterranean, which were established at an early period in the history of the church, no longer exist; those of Asia Minor have disappeared, and in Syria and Palestine, the cradle of Christianity, it still maintains a feeble and uncertain existence.

ARTS AND SCI. DIV. VOL. II.

The great Christian churches are—

1. The Greek, or Eastern Church, divided into four principal branches.
2. The Latin, or Western, or Roman Catholic Church, which is single and undivided.
3. The Protestant Church.

The Protestant cannot be called a Church in the sense in which the Roman Catholic is called a Church, as it is not one undivided community, but consists of numerous independent communities. Still, as distinguished from the Roman Catholic community, the whole body of Protestants is sometimes designated, though improperly, as the Protestant Church.

CHRISTMAS, the festival in memory of Christ's nativity, the day of which is observed on the 25th of December. St. Chrysostom informs us that, in the primitive times, Christmas and Epiphany were celebrated at one and the same feast ('Homil. in Diem Nativ. D. N. J. Christi,' Opera, edit. Montfaucon, tom. iii.), probably from the belief that the rising of the star in the east and the birth of Christ were simultaneous. The separation took place at the Council of Nice, A.D. 325. The Armenians, however, continued to make but one feast of the two, as late as the 13th century.

The learned have long been divided upon the precise day of the Nativity. Some have fixed it at the Passover; others, among whom was archbishop Usher, at the feast of Tabernacles; and it has been observed, that if the shepherds were watching their flocks when it occurred in the field by night, it could hardly have happened in the depth of winter. Be this as it may, the 25th of December has been the day most generally fixed upon from the earliest ages of the Church. Sir Isaac Newton, in his 'Commentary on the Prophecies of Daniel' (Pt. i. c. ii. p. 144), has a chapter, 'Of the Times of the Birth and Passion of our Saviour,' in which he accounts for the choice of the 25th of December, the winter solstice, by showing that not only the feast of the Nativity, but most others, were originally fixed at cardinal points of the year; and that the first Christian calendars having been so arranged by mathematicians at pleasure, without any ground in tradition, the Christians afterwards took up with what they found in the calendars: so long as a fixed time of commemoration was solemnly appointed, they were content. The reader who would know more on this subject may consult Baronii, 'Apparatus ad Annales Ecclesiasticos,' fol. Lucæ, 1740, p. 475, et seq.; Bingham's 'Antiquities of the Christian Church,' lib. xx. cap. 4; and a curious tract entitled, 'The Feast of Feasts; or, the Celebration of the Sacred Nativity of our blessed Lord and Saviour Jesus Christ; grounded upon the Scriptures, and confirmed by the practice of the Christian Church in all ages.' 4to, Oxf. 1644.

The season of the Nativity is no longer marked by that fervid hospitality which characterised its observance among our forefathers. At present, Christmas meetings are chiefly confined to family parties. The wassail-bowl, the yule-clog, and the lord of misrule, with a long train of sports and customs which formerly prevailed at this season, are forgotten: even Christmas carols are nearly gone by; and the decking of churches, and occasionally of houses, with holly and other evergreens, forms now almost the only indication that this great festival is at hand. For the customs formerly prevalent before, at, and about Christmas, see Brand's 'Pop. Antiq.,' edited by Sir Henry Ellis, vol. i.

CHROMATES. [CHROMIUM, *Chromic Acid*.]

CHROMATIC. [ACHROMATIC; LIGHT.]

CHROMATIC SCALE, in music, is the scale of semitones [SCALE]; and by *chromatic music* is commonly signified that kind of harmony in which extreme intervals are much used.

In the Greek music the *chromatic* (from *χρῶμα*, colour) was the second of the three *genera*, and, according to the opinion of some, was so denominated because the notes, or musical characters, in that genus were written in colours. Others think that the word was figuratively employed, and expressed a greater variety of shade, more of contrast, than the other *genera*. Having no data to judge from, it is impossible to say which of the two opinions is the correct one; and, in truth, the question may just as well remain in its present state.

CHROMATIC THERMOMETER. [THERMOMETER.]

CHROME ALUM. [ALUMS.]

CHROME ORANGE. [LEAD, *Dichromate of*.]

CHROME YELLOW. [LEAD, *Chromate of*.]

CHROMIC ACID. [CHROMIUM.]

CHROMIUM (Cr) is one of the elements. It is a metal, but does not occur as such in nature, being always combined with oxygen. As sesquioxide it is found in a mineral called *chrome-ochre*; as chromate of lead, in *red-lead spar*; and as sesquioxide associated with protoxide of iron, in *chrome iron-stone*. The last-mentioned is the most important ore of chromium, but neither of them are very abundant. From the United States and from Norway there are annually imported into Great Britain about 1500 tons of chrome iron-stone; it is all consumed in the manufacture of colouring matters for the use of the painter, the dyer, and the calico-printer. To the latter fact the derivation of the word *chromium* is owing, from *χρῶμα* (*chroma*), colour.

Chromium was first discovered by Vauquelin, in 1797. (VAUQUELIN, Biog. Div.) He obtained it in a more or less fibrous or granular condition, by subjecting chromic acid, or sesquichloride of chromium, mixed with oil and charcoal in a well-luted crucible, to the heat of a

powerful furnace. More recently, M. Fremy has obtained the metal in crystals possessing great brilliancy. They belong to the cubic system, are very hard, and not acted upon by even the strongest acids. The crystals were formed on passing sodium vapour, by means of a stream of hydrogen, over the anhydrous chloride heated to redness.

By heating the sesquichloride of chromium with potassium, and washing the product with water, an allotropic modification of the metal is obtained. It presents the appearance of a dark gray powder, that under the burnisher assumes a metallic lustre. Heated in contact with air, it takes fire at a temperature below redness, and burns with considerable brilliancy, yielding sesquioxide. It is rapidly acted upon by acids, hydrochloric or dilute sulphuric dissolving it with evolution of hydrogen gas.

Chromium is of a light gray colour; its specific gravity is about 5.9. It is very brittle, non-volatile and non-magnetic. From the difficulty of preparing it in the metallic state, as well as on account of its comparative scarcity, this metal has not yet received any application in the arts.

Equivalent, 26.27.

Chromium and oxygen combine to form several compounds. The most important are four in number:—

	Formula.	Equivalent.
Protoxide of chromium	CrO	34.3
Sesquioxide of chromium	Cr ₂ O ₃	76.5
Chromic acid	CrO ₃	50.3
Perchromic acid	Cr ₂ O ₇	108.5

To these may be added *chromoso-chromic oxide* (Cr₃O₄), corresponding to magnetic oxide of iron, and four other oxides, which may be viewed as combinations of sesquioxide of chromium with one, two, three, or four equivalents of chromic acid.

Protoxide of chromium (CrO) cannot be obtained in the anhydrous condition. The *hydrate* (CrO, HO) is precipitated when caustic potash is added to a solution of protochloride of chromium. Its colour is dark brown. It is a very unstable compound, rapidly absorbing oxygen, and becoming converted into a higher oxide. By careful manipulation it may be made to form salts with several of the acids. The double sulphate of protoxide of chromium and potash (CrO, SO₄ + KO, SO₄ + 6Aq) forms crystals of a fine blue colour.

Sesquioxide of chromium (Cr₂O₃). For use in enamel painting and glass staining: this is best prepared by heating chromate of mercury to redness; metallic mercury and oxygen are given off, and the sesquioxide remains as a deep green powder. It may also be obtained by heating bichromate of potash with carbonate of potash and chloride of ammonium, or with sulphur only, or with charcoal, or, finally, by heating bichromate of potash alone; in the latter case the following decomposition takes place:—

The oxide thus prepared presents a beautifully crystalline appearance.

The *hydrated sesquioxide* of chromium (Cr₂O₃, 9HO) is a grayish-green precipitate; and when obtained by adding solution of ammonia to a cold solution of a violet-coloured salt of chromium, is then soluble in ammonia, acetic acid, or dilute solutions of potash; dissolved in strong acids violet-coloured solutions are obtained. Under other circumstances, however, hydrated sesquioxide of chromium possesses properties the very reverse of those just mentioned; its composition remains the same, but it is no longer soluble in ammonia, acetic acid, or dilute solutions of potash; a distinct isomeric condition is set up. Very slight causes are sufficient to effect this modification; thus the action of boiling water, desiccation in the open air, or even in vacuo after some time, or mere friction, are, according to M. Fremy, sufficient to determine this change from the soluble to the insoluble variety.

The *salts of the sesquioxide* of chromium, like the sesquioxide itself, exist under different isomeric modifications. Thus *sulphate of chromium* is obtained of a violet colour, when eight parts of hydrated oxide dried at 212° are digested with nine parts of concentrated sulphuric acid in a shallow vessel for two or three weeks; at the end of that time the mixture is usually converted into a mass of crystals having the composition (Cr₂O₃, 3SO₃, 15HO). With the sulphate of potash, this variety forms a beautiful violet-coloured double salt called *chrome alum*, from the fact that it is in all respects similar to common alum, except that it has chromium in the place of aluminium. [ALUMS.]

The *green sulphate* of chromium is formed when solution of the violet sulphate is boiled; it is uncrystallisable.

A *red anhydrous sulphate* (Cr₂O₃, 3SO₃) is obtained in crystals when either of the preceding sulphates are heated to about 700°. It is quite insoluble in water, or concentrated acids; long contact with water, however, converts it into the soluble variety.

The other salts of sesquioxide of chromium are comparatively unimportant; in general properties the sulphate is a type of them. M. Fremy distinguishes those of a violet colour as *salts of metachromic sesquioxide*, and those possessing a green tint as *salts of the ordinary oxide*. When the former are converted into the latter by ebullition no alteration in chemical composition takes place, the change is entirely

due to the isomeric modification of the oxide contained in them as before adverted to.

Tartrate of chromium (2Cr₂O₃, C₈H₄O₁₀), obtained by digesting hydrated sesquioxide of chromium in solution of tartaric acid. The resulting liquid is deep green by reflected light, and violet by transmitted light.

Bitartrate of chromium (Cr₂O₃, HO, C₈H₄O₁₀), or rather—

Chromotartaric acid (C₈H₅(Cr₂O₃)O₁₂), that is, tartaric acid (C₈H₆O₁₂) in which an equivalent of hydrogen is replaced by (Cr₂O₃). Chromotartaric acid is prepared by adding powdered tartaric acid to a hot aqueous solution of bichromate of potash till evolution of carbonic acid ceases; the re-action is somewhat complicated. By double decomposition with acetate of lead, a bluish green precipitate of chromotartarate of lead is produced, and from this by means of a current of sulphuretted hydrogen the chromotartaric acid is isolated.

Chromic acid (CrO₃) crystallises in beautiful crimson needles on the cooling of a mixture of about four parts of a saturated solution of bichromate of potash, and five parts of concentrated sulphuric acid; on pouring off the mother liquor and draining the crystals for some time on a porous tile, they are obtained nearly pure.

Chromic acid is anhydrous. On being heated it first blackens, at about 400° fuses to a bright reddish-brown liquid, and at a higher temperature is decomposed into oxygen and sesquioxide of chromium. Exposed to the air it rapidly deliquesces. It has a sour, somewhat rough taste, no odour, stains the skin yellow, and rapidly oxidises organic matter.

Chromates, formed by the union of chromic acid with bases, occur in three classes, basic, neutral, and acid; the *dichromate of lead* (orange chrome), containing two equivalents of oxide of lead to one of chromic acid (2PbO, CrO₃) is a familiar instance of a basic chromate; *yellow chromate of lead* (chrome yellow) (PbO, CrO₃) is a well known example of a neutral chromate; while *bichromate of potash* (KO, 2CrO₃) is a type of acid chromates. For details of the preparation and properties of the chromates, see the various metals, LEAD, MERCURY, ZINC, POTASSIUM, &c.; also an excellent paper 'On the manufacture of chromate and bichromate of potash, chromate and bichromate of soda, chromate of lime, chromate and dichromate of lead, chromate of zinc, chromic acid, &c., &c.,' in the 'Pharmaceutical Journal,' vol. xv., pp. 32 and 66.

Bichromate of ammonia. A quantity of chromic acid is divided into two portions, the one neutralised with ammonia and the second portion then added. On evaporating the solution over strong sulphuric acid bichromate of ammonia crystallises, under the form of cherry red prisms; on exposing a few crystals of this salt, placed in a crucible capable of containing twenty or thirty times the quantity, to the flame of a lamp, a very energetic action ensues, accompanied with incandescence, and the crucible is filled with sesquioxide of chromium, in a form in which it presents a perfect resemblance to green tea.

The source of all the salts of chromic acid is of course *chrome iron ore*, which is oxidised either by a nitrate or more simply by atmospheric air.

Perchromic acid (Cr₂O₇) is formed whenever an aqueous solution of peroxide of hydrogen is brought into contact with chromic acid. The liquid assumes a deep blue colour, but is rapidly decomposed with evolution of oxygen; if, however, the solution be agitated with ether the acid is withdrawn from the aqueous portion, and may be made to unite with ammonia or certain organic bases to form tolerably stable compounds. Strong acids decompose the perchromates, and separate blue perchromic acid.

Chromium and chlorine combine to form a protochloride and a sesquichloride.

Protochloride of chromium (CrCl) is formed on passing a current of dry hydrogen gas over the sesquichloride, heated to redness; hydrochloric acid is given off, and the protochloride remains as a white powder. It is soluble in water, yielding a blueish green solution that rapidly absorbs oxygen from the air.

Sesquichloride of chromium (Cr₂Cl₃) is a very beautiful substance, having the form of transparent plates, in colour resembling, but somewhat darker than, peach blossoms. It is readily obtained on passing a current of dry chlorine gas over a mixture of sesquioxide of chromium and charcoal heated to redness in a porcelain tube; the sesquichloride, being volatile, sublimes and condenses in the cool extremity of the tube. It is scarcely altered by even long exposure to air, and if pure is quite insoluble in water or in acids; the presence, however, of a trace of protochloride renders it easily soluble. Solution of sesquichloride of chromium is most readily made by deoxidising a solution of bichromate of potash, containing excess of hydrochloric acid, with either alcohol or sulphite of soda; if required quite pure, the solution may be supersaturated with ammonia, and the precipitated oxide washed and dissolved in hydrochloric acid.

Chlorochromic acid always results when hydrochloric, sulphuric, and chromic acids are heated together; the presence of any water prevents the re-action. To prepare it in the pure state, 10 parts of chloride of sodium are fused with 17 parts of neutral chromate of potash; when cold, the mass is broken up, placed in a retort, and 30 parts of the strongest sulphuric acid added; on gently mixing the ingredients, sufficient heat is generated to volatilise the chlorochromic acid, which distils over, and may be condensed in a cooled receiver.

Chlorochromic acid is an intense red liquid. In the air it emits dense fumes, that have an odour more suffocating, if possible, than chlorine. Brought into contact with ammonia a re-action is set up, that usually is sufficiently energetic to inflame the mixture. Passed through a red-hot porcelain tube the vapour deposits brilliant rhomboidal crystals of sesquioxide of chromium. These crystals are of a dark green colour, and sufficiently hard to cut glass.

Chlorochromic acid (Cr_2ClO_2) may be regarded either as chromic acid (CrO_3) in which 1 equivalent of oxygen is replaced by an equivalent of chlorine, or as 2 equivalents of chromic acid united with 1 equivalent of terchloride of chromium, thus:—

Chromium combines with iodine and bromine, but the compounds formed have not been analysed. The phosphide and sulphide of chromium are not important bodies.

Terfluoride of chromium (CrF_3) is a blood-red liquid, obtained by distilling a mixture of 4 parts of chromate of lead, 3 of powdered fluor spar, and 8 of concentrated sulphuric acid, in a platinum retort. It fumes very strongly in the air, giving off irritating vapours of chromic acid.

Cyanide of chromium (Cr_2Cy_3) is a blueish-gray precipitate produced on mixing solutions of sesquichloride of chromium and cyanide of potassium.

Chromohydrocyanic acid ($\text{Cr}_2\text{Cy}_3, 3\text{HCy}$), or chromocyanide of hydrogen, is a body analogous to hydroferricyanic acid. The potassium salt ($\text{Cr}_2\text{Cy}_3, 3\text{KCy}$), isomorphous with ferricyanide of potassium, is produced on exposing to the air a mixture of caustic potash, hydrated oxide of chromium, and hydrocyanic acid. From this salt other chromocyanides may be obtained by double decomposition. By the action of sulphuretted hydrogen on the silver salt, the acid itself is isolated.

Amido-chromic bases containing chromic oxide (Cr_2O_3) united with several atoms of ammonia (NH_3) have recently been obtained by M. Fremy. An interesting fact connected with these bases is, that the ammonia taken up entirely loses its power of saturating acids. Thus, *roseo-chrome* ($\text{Cr}_2\text{O}_3, 4\text{NH}_3$), like the sesquioxide itself, combines with three equivalents of an acid to form neutral salts; the four equivalents of ammonia which enter into its molecule exercise, therefore, no influence upon its capacity of saturation. The *sulphate of roseo-chrome* ($(\text{Cr}_2\text{O}_3, 4\text{NH}_3), 3\text{SO}_3$) is obtained by acting with sulphuric acid on the violet granular body (*amide of chromium*), that deposits on exposing to the air a solution of metachromic sesquioxide in an ammoniacal salt containing excess of ammonia.

Tests for the salts of chromium. Sesquisalts give a green precipitate (of oxide) with sulphide of ammonium; no precipitate with sulphuretted hydrogen; with ammonia a bulky gelatinous precipitate (of hydrated sesquioxide); with the fixed alkalies a green precipitate, soluble in excess, and reprecipitated on boiling.

Soluble salts of chromic acid give a yellow precipitate (chromate of lead) with lead salts; a red precipitate (chromate of silver) with nitrate of silver; and an orange precipitate (subchromate) with subnitrate of mercury.

The quantitative estimation of chromium is most conveniently performed by obtaining it in the form of chloride, precipitating with ammonia and well washing, and igniting the resulting oxide in a covered platinum crucible; 100 parts contain 68.68 of chromium.

CHROMOHYDROCYANIC ACID. [CHROMIUM, *Cyanides of*.]

CHROMOTARTARIC ACID. [CHROMIUM, *Tartrates of*.]

CHROMULE. [CHLOROPHYLL.]

CHRONICLE, CHRONICON (*χρόνος*, time), denotes a history in which facts are digested in order of time, though not necessarily in successive years, as is distinctly implied in the word *Annals*. It must be owned, however, that the two terms have been indiscriminately used for histories in which the succession of years has been the governing principle of the narrative. The term *chronicle*, at the present day, is seldom used but in speaking of our old histories, as the 'Saxon Chronicle'; 'Caxton's Chronicle'; 'Fabyan's Chronicle'; 'Holinshed's Chronicle'; &c. This term was also adopted by the French, as in 'Froissart's Chronicles', 'Monstrelet's Chronicles', and in 'Les Chroniques de France (appelées la Chronique de St. Denys), compilées par l'ordre du Roy Charles VIII.' [ANNALS.]

CHRONICLES, the name of two books of the Old Testament. In the original Hebrew they constitute only one book, entitled דִּבְרֵי הַיָּמִים (*Dibrē Hayyamim*), *Verba Dierum*, Words of Days; that is, diaries or journals. In the Septuagint they are called Παράλειπόμενα, *res prætermisæ*, "things omitted." The Books of Chronicles have been so called from being considered as supplementary to the Books of Samuel and of Kings; the histories of which they repeat with considerable variations. The name *Chronicles* seems to have been first applied by St. Hieronymus (Jerome). Much difference of opinion has been entertained as to the compilers; but the general tendency of all critical opinion, ancient and modern, ascribes the authorship to Ezra, after the return of the Jews from the seventy years' captivity in Babylon. Eichhorn enumerates several reasons for attributing them to Ezra ('*Einleitung*,' vol. ii.), one of which is a similarity to the books of Kings and Ezra in style, orthography, and idiom; but this assumes that Kings was written by Ezra, an opinion not now generally entertained.

The Jews also ascribe them to Ezra. Several objections have, however, been taken as to the probability of their being his work (Calmet's 'Dict.' by Taylor), one of which is, that (Chron. iii. 19, *et seq.*) an account is given of the posterity of his contemporary Zerubbabel, which extends to nine generations, or about 300 years, beyond the time of Ezra; but nothing, as Eichhorn observes, is certainly known of the time either of Ezra's birth or his death, and nothing is more likely than that a genealogy of the house of David, a matter of great interest to the Jews, should have been interpolated by a later hand. An objection has also been raised on account of certain discrepancies between the statements in the books of Chronicles and of Kings, on the supposition that if Ezra compiled Kings he would not have contradicted himself in Chronicles. But the most likely theory is that Kings was compiled by Jeremiah. Dr. A. Dillman (in Herzog's 'Real Encyclopädie,' 1853) contends that the Books of Chronicles must have been written about 330 B.C., but that they and Nehemiah also contain fragments of the older composition. The Rev. T. H. Horne ('Introduction to the Holy Scriptures') also decides against the authorship of Ezra.

The numerous contradictions throughout Chronicles and Kings, in facts, dates, numbers, names, and genealogies, are acknowledged by many learned critics. They form the subject matter of nearly the whole of Dr. Kennicott's 'First Dissertation on the State of the Hebrew Text;' where they are treated as corruptions, interpolations, and mistakes. In the narrative 1 Chron. xviii. 3, which is taken verbatim from 2 Sam. viii. 3, there occurs, besides a variation of proper names, an alteration of 700 horsemen to 7000: and exactly "the same mistake" (Kennicott) occurs in the passage cited in 1 Chron. xix. 18, from 2 Sam. x. 8. Compare also the numbers in 1 Kings iv. 26, with 2 Chron. ix. 25; and 1 Kings ix. 23, with 2 Chron. viii. 18; and the statement of Ahaziah's age in reference to that of his father, in Chron. xxi. Most, if not all these apparent inconsistencies, are, however, reconcilable, and this has been well done by Dahler and Keil, Eichhorn and Häverneck, in Germany, and by Dr. Kitto in the 'Pictorial Bible,' and Dr. S. Davidson in his 'Sacred Hermeneutics.' Spinoza, De Wette, and Gramberg have been the most strenuous opponents to the credibility of the books of Chronicles.

Many passages and chapters in Chronicles and Kings appear to have been transcribed verbatim from records made before the Babylonian captivity, while the Temple was standing: as 2 Chron. v. and 1 Kings viii., which are word for word alike, and speak of the ark, the former in v. 9, the latter in v. 8, as being in the Holy Place "unto this day;" though neither Kings nor Chronicles are supposed to have been written until from sixty to ninety years after the Temple, and all its contents had been demolished, or carried off by Nebuchadnezzar. Another instance is in 2 Chron. viii. 8. The last thirteen verses of 1 Chron. i., occur verbatim in Genesis xxxvi., and appear to have been transcribed from some historical document made after Saul, the first king, reigned in Israel (see v. 31), which was 400 years after the death of Moses. Another curious particular is that the two last verses of 2 Chron. concerning the proclamation of Cyrus, are the same which begin the following books of Ezra. This has been shown by Grotius to have been merely a mark of continuation in ancient books, and that it was so used by Procopius in his 'Hist. Vandalicorum et Gothicorum.' The broken sentence with which Chronicles end at "go up," is completed in v. 3 of Ezra "to Jerusalem," &c.

To this may be added a fact not noticed by the commentators, that the Jews, in the public reading of their scriptures, to avoid ending with the recital of any calamity producing dejection, add the commencement of the next paragraph, or repeat a portion of that which precedes, in order to finish with something consolatory. Accordingly, in Hebrew copies, at the end especially of Isaiah, Malachi, Lamentations, and Ecclesiastes, a masoretic sign is given, formed of the initials of these four books (יהקיה) to indicate the recital of some antecedent

or subsequent passage. It is supposed by St. Hieronymus that the present books of Chronicles are those of the kings of Judah and of Israel, so often referred to in the books of Kings. The objection to this supposition is, that these references are not unfrequently made to what is not to be found in the present book of Chronicles. The Chronicles referred to in Kings are generally thought to have been a voluminous work from which ours are only a brief and mutilated abstract. Grotius, Capellus, Spinoza, Clericus, R. Simonius, Whiston, and others, hold this opinion. The chief design of this compilation seems to have been to exhibit, first, the genealogies, ranks, and functions of the priesthood, in order that, after returning from the captivity, they might re-assume their proper dignities; and secondly, by describing the distribution of lands before the captivity, to direct the families of each tribe in regaining their ancient inheritances. The first book is a recapitulation of sacred history from the creation to the death of David. The second book gives the history of the kings of Israel and Judah from Solomon to the return from Babylon. The authority of the books of Chronicles is established by St. Paul applying a prophetic passage (Heb. i. 5) to the character of our Saviour from 1 Chron. xvii. 13 and 14; see also chap. xxii. 10. (Bishop Mant's 'Bible.') For the purpose of comparison and critical investigation, see the table of Chronicles, Samuel, and Kings, in Horne's 'Introduction to the Bible,' also Cruttwell's 'Concordance of Parallels.' The

books of Chronicles contain many striking and beautiful passages, such as David's prayer and thanksgiving for the people's offerings towards building the temple; Abijah's address to Jereboam; Asa's prayer before the battle against Zerah the Ethiopian; and many others.

CHRONOLOGY (from the Greek word *χρονολογία*), literally signifies "time-reckoning." In contradistinction to history, which connects events according to the manner in which each is produced or occasioned by another, chronology regards events simply according to the order of time. It is evident, however, that the succession of events in the order of time makes a very important part of their exposition in the relation of cause and effect; for whatever else there may be in the bond which unites what we call a cause and its effect, the circumstance that the cause precedes the effect in the order of time is always present. A history therefore cannot be written even in the loosest manner, nor an intelligible narrative put together, without chronology being so far attended to that the events shall be related in the order in which they happened. Even what is called the epic method of taking up the story in the thick of the interest rather than from the beginning of the series of events out of which the interest grows, is no exception. In whatever mode it may be thought best for the effect intended to be produced that the several portions of the story should be arranged and exhibited, each portion must in itself be detailed chronologically, else it will be incomprehensible. And even in an epic poem an order of time is always strictly observed throughout, though the poet may select a different series of events through which to take his course from that which would be adopted by the historian. In the *Æneid*, for example, it is true that the events of the shipwreck of *Æneas* and his followers, and their reception by Queen Dido, which are related in the first book of the poem, happened subsequently to the destruction of Troy, and their adventures in the course of their navigation to Carthage, which pass before the reader in the second and third books; but these last-mentioned events are really not what the poet professes to relate in these two books. What they profess to contain is the discourse addressed by *Æneas* to Dido, at the banquet in her palace; and the delivery of this discourse happened not before but after the events related in the first book of the poem.

The order of a history, however, will often differ from that of a purely chronological arrangement in this respect. In the former each connected series of events is related separately, and thus form a unity, in which the progress and development of certain principles, causes, or given conditions of society are exhibited. In the latter, events of various naturally distinct series are necessarily intermixed, nothing being attended to except the order of time in which they happened. Thus a mere chronological table, or chronicle, of the events of the last century would enumerate, under no arrangement except the order of time, the events which had taken place during that period in all the countries of the world, and in all the departments of human action, and also it might be of inanimate nature; if the scheme were comprehensive enough, the notice of an inundation of the ocean, or an eruption of Vesuvius, might break in upon the detail of a succession of scientific discoveries, or the incidents of a political revolution. History, in the pursuit of its proper business of tracing each effect to its cause, necessarily avoids this intermixture. It follows one chain of events, at least up to a certain point at which a pause may conveniently be made, and then it takes up another chain. Still each chain is continued in the chronological order of its links. Every long history, indeed, must in this way be properly a collection of many short histories; and these latter will be numerous in proportion to the extent and complexity of the subject. Neither a history nor a chronicle need embrace all the recorded or remarkable events of the period over which it professes to extend; the one as well as the other may be confined to events or transactions of any particular kind, as well as of any particular period. But whatever variety of matters may be comprehended in a history, it is at the option of the historian, and belongs to his art, to dispose them into as many distinct narratives, or portions of a narrative, as may appear best suited for their clear and effective exposition; whereas all the facts, however various, which a chronicle or chronological table may comprehend, must be related in one narrative or series. Though an intermixture of all kinds of events with those that more peculiarly belong to chronology, which are the events of political society, is not unusual in tables of chronology, the events of any one branch of human action or speculation, or, as already observed, the phenomena of nature, might often with more propriety be exhibited in separate chronological tables.

It has sometimes been attempted to combine in a chronological table, with its own peculiar advantages, something of this distinctness or separation of one subject from another which is found in a history, by employing a particular form of type or other appropriated mark for each series of connected events. This method was first employed, as far as we know, and indeed it is there claimed as new, in a short general chronological table at the end of the work entitled '*Elements of General History*,' by Alexander Fraser Tytler (afterwards Lord Woodhouselee), 2 vols., 8vo., Edinburgh, 1801. In this table the series of the kings and emperors of Rome is printed in a larger Roman type than the rest of the table, that of the emperors of Germany in Italic capitals, that of the kings of England in the old English letter, that of the kings of France in small Italics, &c. "By this method," to quote the explanation of the compiler, "the succession of the sovereigns in

the different kingdoms is immediately distinguishable to the eye, as well as the duration of their reigns, while the intervening space is filled by the remarkable events that occurred at that period all over the world; and thus the connection of general history is preserved unbroken."

Some histories are written in a more, some in a less strict chronological order. It is observed by Dionysius of Halicarnassus, in a comparison between Herodotus and Thucydides, that Thucydides has followed the order of time, Herodotus that of things, and that on this account Thucydides is obscure and difficult to understand. While Thucydides, he says, has divided his single subject into many parts, Herodotus, having in his history embraced many different subjects, has formed them into a single whole, of which the several parts perfectly correspond. But though the method of Herodotus may be the best adapted for conveying a clear view of each particular portion of history of which he has treated, every series of naturally connected events forming a narrative or story by itself, it is not easy to gather from his work any notion of the synchronism of events, or of the relation of those of one series to those of another in point of time. Larcher, in the preface to his French translation of Herodotus (edition of 1802), has noticed that Photius has complained of the confusion occasioned by the digressions of this author, and that other critics have been disposed to deny that he followed any regular or intelligible plan. Larcher, however, dissents from this judgment, and explains what he conceives to have been the plan of Herodotus ('Preface,' pp. xxv.-xxxii.) He has also printed, with annotations, in his sixth volume, three memoirs by the Abbé Geinoz, in vindication of Herodotus against the attacks of Plutarch; and of these the third (pp. 601-627) is an exposition of the method and plan of the historian. His history is of the form of an epic poem, of which the main subject is the wars of the Greeks and Persians. The digressions, which correspond to the episodes of an epic poem, and, as in the case of that on Egypt, take up an entire book, render it very difficult for a young student to form an idea of the history as a whole. But if the episodes are cut out, the whole history exhibits the main subject in a regular progress and order. The chronological system of Herodotus has been amply illustrated by Larcher, in his '*Essai de Chronologie sur Hérodote*,' printed in the sixth volume of his first edition (1786), and, greatly altered and enlarged, in the seventh volume of his second edition.

But although both Herodotus and Thucydides have, each after his own method, so far adhered to a chronological arrangement as to relate the events in the order of time in which they happened, neither of these writers has throughout his narrative attended to chronology in any scientific sense. They were both prevented from doing this by the want, in that early age, of any fixed epoch or starting-point from which to reckon. It has been well observed, that "the best simile for dates is to say, that they are to history what the latitude and longitude are to navigation—fixing the exact position of, and serving as unerring guides to, the object to which they are applied." (Nicolas's '*Chronology of History*,' preface, p. vi.) In this view the histories of Herodotus and Thucydides may be compared to charts or maps drawn without the aid of parallels of latitude or meridian lines, in which indeed, the situations of cities and mountains, the courses of rivers, and the general form of countries and outline of coasts, might be represented with a certain degree of correctness, but not with the precision requisite for any scientific purpose. Thucydides, however, in recording the events of the Peloponnesian war, keeps to the order of the years; and he fixes the date of the commencement of the war (ii. 2), by referring to the truce made after the capture of Eubœa, to the priesthood of Chrysis in Argos, to the ephorship of Ainesias at Sparta, and the archonship of Pythodorus at Athens. In speaking of events that happened long before the war (i. 13, 19), he refers to the end of the Peloponnesian war as the point from which to reckon backwards.

The determination of the length of the year and the regulation of the calendar appear to have occupied the attention of the ancients, before they ever thought of dating events from a fixed epoch. But the latter object was of interest only to historical inquirers; the former matters were naturally in the hands of the cultivators of astronomy, who were the best qualified for their management, and were besides more immediately interesting and important to the whole community. There is a curious passage in the '*Clouds*' of Aristophanes, in which the clouds, addressing the people of Athens, report a complaint made by the moon, about the displeasure she had incurred from the gods in consequence of the confusion into which their festival days had fallen; the allusion, it has been supposed, being to Meton's reformation of the calendar, which had recently been introduced. ('*Clouds*,' 603, &c.) Aristophanes was a contemporary of Thucydides.

The first æra, or computation of time from an epoch, made use of among the Greeks was that of the Olympiads. "Hail, venerable Olympiads, ye guardians of time, ye vindicators of the truth of history, ye bridlers in of the fanatical licence of chronologists!" exclaims Joseph Scaliger, in his '*Animadversions on Eusebius*,' in a paroxysm of chronological enthusiasm. The date of the original institution of the Olympic games is placed in very remote antiquity; but it was a long time even after their revival by king Iphitus (B.C. 884) before they came to be used for the purpose of fixing historical events. The following paragraph is from the introduction to Playfair's '*Chronology*,'

with the exception of the dates within brackets: "Hellanicus [B.C. 496-411] regulated his narration by the succession of the priestesses of Juno at Argos. Ephorus [B.C. 300] digested things by generations. The Arundelian marbles [B.C. 263] make no mention of olympiads, and reckon backwards from the time then present by years. In the histories of Herodotus [B.C. 484-413] and Thucydides [B.C. 471-391] the dates of events are not ascertained by any fixed epochs. The olympiads were not commonly applied to this purpose in so early a period. Timæus of Sicily, who flourished in the reign of Ptolemy Philadelphus [B.C. 283-245], was the first who attempted to establish an æra, by comparing and correcting the dates of the olympiads, the Spartan kings, the archons of Athens, and the priestesses of Juno. Eratosthenes [B.C. 194], the father of chronology, and Apollodorus [B.C. 115] digested the events recorded by them, according to the olympiads and the succession of Spartan kings." When the olympiads were adopted as an æra, the reckoning was made to commence from the games at which Coræbus was the victor, being the first at which the name of the victor was recorded. The olympiad of Coræbus accordingly is considered in chronology as the first olympiad. Its date is placed 108 years after the restoration of the games by Iphitus, and is calculated to correspond with the year B.C. 776.

The statement we have just quoted from Playfair is given at greater length, and with references to the authorities, in the first chapter of Sir Isaac Newton's 'Chronology.' Of the names that have been mentioned, only Eratosthenes and Apollodorus can be considered as having been systematising chronologers, or as having employed themselves on the science of chronology. The merits of Timæus appear to have consisted in his endeavouring to ascertain with greater precision than any preceding historian the dates of the events of which he treated in his histories of Sicily, of the wars of Pyrrhus, &c. An account of his works is given in Clinton's 'Fasti Hellenici,' iii. 489-491. The fragments of Timæus have been collected by Goeller, in his work, 'De Situ et Origine Syracusanorum,' 8vo, Leipzig, 1818. Eratosthenes, the eminent astronomer, seems to have endeavoured to establish what may be called a system of chronology by ascertaining the dates of certain ancient events, which might serve as fixed points from which to reckon all other events. We have no account however of the process by which he arrived at his conclusions. The fragments of his chronological as well as of his other writings, with the passages of the ancient authors in which each is mentioned, and notes, have been published by Gottfr. Bernhardt in a small volume, entitled 'Eratosthenica,' 8vo., Berolini, 1822. The dates which he affixed to the principal events of antiquity are given from Clemens Alexandrinus, in Clinton, i. 124. Those of Apollodorus, who made some corrections on the system of Eratosthenes, are given in Clinton, i. 125, as preserved by Eusebius on the authority of Porphyry. Clinton has shown that the leading dates of Eratosthenes and Apollodorus were adopted generally by subsequent chronologers, both Greek and Latin. Among the Romans the most eminent authority in chronology was Varro, who flourished in the century immediately preceding our æra, but of whose numerous and learned works very little remains. Belonging to a much later age, the 3rd century of our æra, there has been preserved the work of Censorinus, entitled 'De Die Natali,' which is in the greater part a treatise on dates, epochs, and other matters appertaining to the science of chronology. There is a passage in the twenty-first chapter of Censorinus, containing a memorandum of the distance of the year in which he wrote (A.D. 238) from the first olympiad, from the building of Rome, from the reformation of the calendar by Julius Cæsar, and from other epochs, which has been thought so important to chronology, that Petau has attributed its preservation to the special goodness of Providence.

The establishment of the first olympiad as a common epoch may be said to have given birth to chronology as a science, by introducing into historical writing the general practice of dating events with reference either to that or to some other fixed point. The principal business of chronologers after this was to determine the relationship of each of these epochs to every other.

The common æra of the Roman historians commences from the foundation of the city of Rome. But there was a great variety of opinion among the ancients, as there has continued to be among the moderns, respecting the true date of this event. The Romans themselves for the most part followed either the computation of Cato, which places it in B.C. 752, or that of Varro, which assigns it to B.C. 753. Some writers, among others Livy, appear to reckon sometimes by the one, sometimes by the other; most modern chronologers follow that of Varro. This practice of dating events from the building of Rome may be regarded as the first adoption of the simple method of reckoning from a fixed point by single years, and as forming therefore one of the great stages of chronology.

Another usual mode of reckoning among the Latin historians was by the annual consulships. Often both the year of the city and the names of the consuls are given.

The method of reckoning from the first olympiad was occasionally employed long after the birth of Christ. "Some writers," says Playfair, "have continued the use of the olympiads to the 312th year of the Christian era. Cedrenus (a Greek monk of the 11th century) has brought them 80 years lower, making the 393rd year of our Lord the last olympian year." Sir Harris Nicolas ('Chronology of History,' p. 2) speaks of the computation by olympiads having ceased after the

364th olympiad, in the year of Christ 440. Particular writers may have reckoned by olympiads down to that date, as they might down to the present day; but it had certainly long before ceased to be the common practice to do so. From A.D. 312 the regular public mode of computation throughout the Roman empire, both west and east, was by the indictions, which were cycles or periods of fifteen years, beginning with that year. [INDICTION.] The practice of dating events by indictions was at one time followed in most of the kingdoms of modern Europe, and in France was not altogether discontinued till the end of the 15th century. The method of dating events from the birth of Christ is said to have been first practised by a Roman monk named Dionysius the Little about the year 527. It came into general use in Italy before the termination of that century, but in France not until the 8th century, in Spain not until the 14th, and in Portugal not till after the commencement of the 15th. The method of reckoning from this epoch, being now universally adopted throughout Christendom, and being the only computation generally used both in historical accounts of past events and in dating current time, has furnished a chronological measure of much more extensive application than any other which had preceded it. It is generally held that the birth of Christ actually took place about four years earlier than the date assigned to the event by Dionysius; but this mistake of the inventor of the vulgar æra does not affect its value as a scheme of chronological notation. It is quite unimportant which the point is from which we reckon, if it be a determinate point.

There is one inconvenience however attending the choice of an event for reckoning from so recent as the birth of Christ, namely, that it necessarily introduces two modes of reckoning, and leaves the events of a large, in fact of the largest, portion of history to be as it were dated backwards, or according to the distance of each behind the assumed epoch. Even the era of the olympiads was not free from this objection; for although, as we learn from Censorinus, Varro considered the historical age to commence only with the first olympiad, the traditions even of the Greeks ascended to fully four hundred years beyond that date. The histories and traditions of the Hebrews, and other ancient nations, extend much farther back. To provide a more comprehensive mode of reckoning, Joseph Scaliger, in 1582, invented what he called (after Julius Cæsar) the Julian period, being a cycle of 7980 years, which was made to begin at the year 4713 B.C. [PERIODS OF REVOLUTION.] A period still more remote of 15,969 years was invented by Jean Louis d'Amiens, and named the Louisian, in honour of Louis XIV., but this has been very seldom used.

If the date of the creation of the world, or rather of man's appearance on the earth, could be certainly established, that would form the natural and most convenient point from which to commence the reckoning of time and to date the events of human history. None of the ancient chronologers attempted to fix this point; a common opinion then held was, that the world was eternal: some conceived that any attempt to discover the commencement of its existence would be an act of impiety. Even among the Jews and Christians, whose sacred writings begin their record of events from the creation, there has been the greatest diversity of opinion as to that epoch. Kennedy in his 'Scripture Chronology,' affirms that 300 different opinions might be collected as to the length of time that elapsed between the creation and the incarnation. John Alb. Fabricius, in his 'Bibliotheca Antiquaria,' has given a list of 140 of these determinations. Dr. Hales, in his 'New Analysis of Chronology,' has collected above 120. In 'L'Art de vérifier les Dates,' vol. i., p. 27, &c., is given a list of 108. Playfair has given one of 88. Desvignoles, in the preface to his 'Chronology of Sacred History,' asserts that he has collected above 200 such calculations, of which the longest makes the distance between the two points to have been 6984, and the shortest only 3483 years.

The uncertainty and controversy upon this subject have been principally occasioned by the disagreement in the ages assigned to the Patriarchs, and in other numbers, between the Hebrew text of the Old Testament and the texts of the Samaritan and Septuagint versions. From the creation to the deluge the computation of the Hebrew text makes 1656 years to have elapsed; the Samaritan version only 1307; and the Septuagint 2262. The common opinion of modern theologians, and also of chronologers, has been that the Hebrew text is correct; and it is upon this assumption that Archbishop Usher, whose reckoning has been most generally adopted, has fixed the distance between the creation and the birth of Christ at 4004 years. But those who hold a contrary opinion, although the least numerous, have, according to Bayle, been usually *des savans d'élite*, inquirers of a superior order. It is maintained by Father Pezron, in his work 'De l'Antiquité des Temps,' that the Hebrew text was designedly corrupted by the Jews in the first century, and the time that had elapsed from the creation made to appear shorter than it really was, in order to meet the argument derived from what is said to have been an old Jewish tradition, that the coming of the Messiah should take place when the world was 6000 years old. Rabbi Akiba is supposed by Pezron to have been the author of the falsifications. Pezron makes the world to have been 5872 years old at the birth of Christ. The supposition of the corruption of the Hebrew text, and the preference due to the Greek translation of the LXX., has been adopted and supported by Dr. Hales, who will scarcely however be reckoned one of the *savans d'élite*.

Among modern systems of chronology, one of the most remarkable and peculiar is that proposed by Sir Isaac Newton, in his posthumous work, 'the Chronology of Ancient Kingdoms Amended,' 4to, London, 1728. Newton, assuming the nearly entire valuelessness of the determinations of the dates of ancient events by the Greek chronologists and their followers, proceeds to form a new system on considerations wholly independent of their authority. In the first place he has endeavoured to show that the ancient historians, when "a little after the death of Alexander the Great, they began to set down the generations, reigns, and successions, in numbers of years, by putting reigns and successions equipollent to generations, and three generations to 100 or 120 years (as appears by their chronology), have made the antiquities of Greece 300 or 400 years older than the truth." He contends that the reigns of kings, on an average, do not exceed eighteen or twenty years. Secondly, he has endeavoured to ascertain the date of the famous Argonautic expedition by an ingenious calculation founded upon the known precession of the equinoxes at the rate of a degree in seventy-two years (properly a degree is about $71\frac{1}{4}$ years), and the assumption of the equinoctial and solstitial colures having at the time of the expedition cut the ecliptic in the cardinal points. From these data he determines the expedition to have taken place about the year 928 B.C., which gives an antiquity less by about three centuries than that commonly assigned to the event. But the grounds on which Newton had assumed the position of the colures at the time of the expedition are now generally acknowledged to be quite insufficient. Although the full exposition of this system was not published till after the death of the author, its general principles got abroad during his lifetime, and were attacked from various quarters. The two chief early assailants of the Newtonian chronology were the learned French Jesuit Souciet, and Nicolas Freret, known for his many valuable contributions to the memoirs of the Academy of Inscriptions. In latter times the system has been examined by Playfair (pp. 35-37), and by Hales (vol. i., pp. 26-29). See also Sir David Brewster's 'Life of Newton,' and a valuable note by M. Daunon to the article on Newton by Biot in the 'Biographie Universelle,' vol. xxxi., pp. 180-186. Clinton denies that the general uncertainty of the early Greek chronology is so great as is supposed by the scheme of Newton.

Although Newton's deduction of the date of the Argonautic expedition from the precession of the equinoxes cannot be depended on, owing to the want of any authority for the position of the colures at the time of the expedition, the science of astronomy has in another way rendered valuable assistance to that of chronology. This it has done by the means which it affords of ascertaining the exact date of many eclipses of the sun and moon which are recorded by ancient writers, and are sometimes connected by them with historical events that happened at or near the same time. In the first volume of the great French work, 'L'Art de Vérifier les Dates' (pp. 146-265), are given lists of all the eclipses of the sun and moon which could have been seen to the north of the equator for ten centuries preceding the birth of Christ; and secondly, of all those recorded before that epoch by ancient writers. In a subsequent volume of the same work there is inserted a list of the visible eclipses that have happened since the commencement of the vulgar era. Lists of eclipses, solar and lunar, are also given in Playfair's 'Chronology,' pp. 175-219. As an example of the astronomical examination of a recorded ancient eclipse, see the article ALYATTES, in BIOG. DIV.

One of the earliest of the Christian systematic chronologists is Sextus Julius Africanus, who appears to have flourished in the first half of the 3rd century. Of his chronological work, entitled 'Pentabiblos,' however, beginning with the creation, which he dated B.C. 5499, and ending with A.D. 221, only some fragments remain. [AFRICANUS, BIOG. DIV.] The most important of the works of the early Christian chronologists which we now possess is the Chronicon of Eusebius Pamphili, bishop of Caesarea, in the 4th century, of which an edition was published with notes by Joseph Scaliger in 1658, in one volume folio, containing the Latin translation by St. Jerome, and Scaliger's attempted restoration of the lost Greek text. The Armenian version of the Chronicon of Eusebius, which is more complete than the previous editions, was published at Venice in 1818, with a literal Latin translation, and another Latin translation of it, in the same year, at Milan. There is a famous Spanish commentary upon the Chronicle of Eusebius, by Alfonso Tostato, printed at Salamanca, in 5 vols. fol., in 1506. The work which is to be considered as having laid the foundation of the modern science of chronology is that of Joseph Scaliger, 'De Emendatione Temporum,' first published in folio at Paris in 1583, and afterwards, much augmented and amended, at Leyden in 1598, and at Geneva in 1629. Another important work of that age is that of Dionysius Petavius, or Petau, 'De Doctrina Temporum,' 2 vols. fol., Paris, 1627, with the Continuation in 1 vol. fol., Paris, 1630, entitled 'Uranologion, sive Systema variorum auctorum qui de Sphæra ac Sideribus, &c., commentati sunt.' An abridgment of this work, under the title of 'Rationarium Temporum,' was published at Paris in 8vo, in 1630, and has been several times reprinted. Of other early Continental works on chronology, the following are some of the most valuable, or the most celebrated:—Sethi Calvisii, 'Opus Chronologicum,' Leips. 1603, often reprinted; J. Bapt. Riccioli, 'Chronologia Reformata,' 2 vols. fol., Bonon. 1669; 'L'Antiquité des Temps rétablie et défendue,' par le Père Paul Pezron, Paris, 4to, 1687, and the Defence

of that work by the author, Paris, 4to, 1691; Hier. Wecchietti Florentini, 'Opus de Anno Primitivo ab exordio Mundi ad Annum Julianum accommodato,' fol., August. Vindel., 1621, a work for which the learned and unfortunate author was shut up during the remainder of his life in the prisons of the Inquisition, his crime being his maintenance of the opinion that Christ did not celebrate the passover the last year of his life, and, in instituting the Eucharist, did not make use of unleavened bread; Philippi Labbe et Philippi Brietii, 'Chronologia Historica,' 5 vols. fol., Paris, 1670; 'Chronologie de l'Histoire Sainte,' par Alphonse Desvignoles, 2 vols. 4to, Berlin, 1738. The work of the Benedictine monks, Maur d'Antine, Durand, and Clemencé, first published in 1 vol. 4to, at Paris, 1750, and which, in the latest edition, extending to 38 vols. 8vo, published at Paris, 1818-31, under the title of 'L'Art de Vérifier les Dates, ou la suite Chronologique des événements remarquables depuis la création du monde jusqu'en 1828,' has become the most extensive and important work on general chronology that exists. The principal works by English authors upon this science are the 'Chronicus Canon Ægyptiacus, Ebraicus, et Græcus,' of Sir John Marsham, fol., London, 1672, and also Leipzig, 1676, and Francfort, 1696; Archbishop Usher's 'Annales Utriusque Testamenti,' fol., Lond. 1650, and several times reprinted; Sir Isaac Newton's work, already noticed; Jackson's 'Chronological Antiquities,' 3 vols. 4to, 1752; Blair's 'Chronology and History of the World, from the Creation,' fol., 1754; again, 1768, with additions; and in 1857, in post 8vo, with very large additions, brought down to the date of publication,—a very useful work, but one that admits of some improvements in the arrangement, the dates of events occurring in any one year being too much scattered; Kennedy's 'Complete System of Astronomical Chronology, unfolding the Scriptures,' 4to, 1762; Playfair's 'System of Chronology,' fol., Edin. 1784; and the Rev. Dr. William Hales's 'New Analysis of Chronology, in which an attempt is made to explain the History and Antiquities of the Primitive Nations of the World, and the Prophecies relating to them,' 3 vols. 4to, 1800-1812. There is also a useful introduction to chronology by Bishop Beveridge, entitled 'Institutionum Chronologicarum Libri Duo, una cum totidem Arithmetices Chronologicæ Libellis,' 8vo, Lond. 1669, and several times reprinted. There are many good works on chronology in foreign languages, among which may be specially mentioned Ideler's 'Handbuch der mathematischen und technischen Chronologie,' Berlin, 1825-26. Particular portions of ancient chronology have been ably illustrated by Corsini in his 'Fasti Attici, in quibus Archontum Atheniensium series, Philosophorum, aliorumque illustrium virorum ætas, atque præcipua Atticæ Historiæ capita, describuntur,' 4 vols. 4to, Flor. 1744-61; by Wesseling, in his edition of Diodorus Siculus, 2 vols. fol., Amster. 1745; by Dodwell, in his 'Annales Thucydidei et Xenophontei,' 4to, Oxford, 1702; and by Larcher, in his 'Essai de Chronologie sur Hérodote,' already mentioned. But in so far as the Greek chronology is concerned, the most comprehensive, elaborate, and valuable work that has appeared is that of Mr. H. F. Clinton, entitled 'Fasti Hellenici: the Civil and Literary Chronology of Greece, from the earliest accounts to the death of Augustus,' in 3 vols. 4to, of which the first, comprising the chronology from the earliest accounts to the time of Pisistratus, was published at Oxford in 1834; the second, comprising the period from Pisistratus to Ptolemy Philadelphus, in 1824; and the third, completing the review to the end of the reign of Augustus, in 1830.

The volumes of chronological tables that have appeared are too many to be enumerated. Several of the systematic works on chronology that have been mentioned contain collections of such tables. The only other work which we shall mention is a most useful and, as far as we have examined it, very accurate publication, in one small volume, by Sir Harris Nicolas, entitled 'The Chronology of History,' which originally formed one of the volumes of Dr. Lardner's 'Cabinet Cyclopædia.'

[See the articles ÆRA, EPACT, EPOCH, CYCLE, DAY, MONTH, YEAR, INDICITION, &c.]

CHRONOMETER. [HOROLOGY.]

CHRONOMETER, in music, an instrument by which the movement, or time (that is, the quickness or slowness) of a composition is determined.

The musical chronometer is by no means a modern contrivance. So far back as the year 1636 Mersenne described and recommended it, in his 'Harmonie Universelle'; and Malcolm, a sensible writer, urged its use more than a century ago. Yet, owing to the prejudices of musicians, it has till lately not been employed, although its utility has been generally admitted. Dr. Crotch, an enlightened professor, advocated the use of a pendulum. The opponents of a *time-measurer* presume that it is meant rigorously to govern the *whole* of a composition, and that thus the beautiful effects of acceleration and retardation are to be sacrificed; but those who have advised the employment of a pendulum never contemplated its being used for any other purpose than to indicate the time to be adopted at the commencement of a movement. From the want or neglect of some contrivance by which the intention of composers might have been transmitted, we are now obliged to guess the true movements of the most classical works; and it is notorious that many compositions of the highest excellence, and among them several of recent date, are frequently performed in times which could not have been intended, because by good critics admitted to be exceedingly prejudicial to their effect. The invention, by the ingenious M. Maelzel, of a most accurate and convenient machine which he calls a Metronome, is beginning to convince musicians of the

utility of a pendulum; and we are persuaded that not many years will elapse before it will be universally adopted, both by composers and performers. That an advance has been made in its use is evident from the fact, that some composers and editors at the commencement of their printed pieces, now mark the time as indicated by the METRONOME.

CHRYODINE. A dark violet-coloured matter, produced by the action of sulphuric acid upon chrysammic acid.

CHRYSAMIDE. [CHRYSAMMIC ACID.]

CHRYSAMIDIC ACID. [CHRYSAMMIC ACID.]

CHRYSAMMIC ACID ($C_{14}H_2(NO_4)_2O_4$), is the product of the action of nitric acid upon extract of aloes. One part of the extract is heated in a capacious retort with eight parts of nitric acid of sp. gr. 1.37, and the mixture distilled till two-thirds of the nitric acid has passed over; an additional three or four parts of nitric acid is now added, and the whole kept at a temperature a little below the boiling point till no more gas is evolved. The re-action is complete in about three or four days, and on diluting the resulting liquid with water, chrysammic acid is precipitated, which, after washing with a little water, should present the appearance of a sparkling grayish-yellow powder; probably, however, it will be contaminated with a little aloetic acid [ALOETIC ACID], on account of insufficient oxidation. In that case it must be treated with a cold solution of carbonate of potash; the very soluble aloetate of potash separated by filtration and washing from the slightly soluble chrysammate of potash, and the latter dissolved in boiling water, and the chrysammic acid precipitated by nitric acid.

Thus obtained, the chrysammic acid is quite pure. It has the form of golden-yellow lustrous plates, is very slightly soluble in cold water, but a little more so in boiling water, yielding a solution of a purple-red tint, and a bitter taste. It is also soluble in alcohol, ether, and strong acids. Heated chrysammic acid decomposes with violent explosion, producing nitrous vapours and an odour resembling oil of bitter almonds.

The *chrysammates* containing an equivalent of a metal in the place of an equivalent of hydrogen in the chrysammic acid, are remarkable for their slight solubility. The crystalline salts have a greenish gold colour, and the insoluble amorphous salts take the same tint on rubbing with a hard body.

Chrysammate of potash ($C_{14}HK(NO_4)_2O_4$) crystallises in the form of flat rhomboidal plates, that possess an interesting polarising action upon light transmitted through them.

Chrysatic acid (Schunk's *aloeresinic acid*) is the name given by Mulder to an acid obtained on boiling chrysammic acid with caustic potash, and precipitating with an acid. It has a deep brown colour, and forms salts with most of the bases.

Chryiodine is the product of the action of concentrated boiling sulphuric acid on chrysammic acid. Its colour is intense violet. It has not been particularly examined.

Chrysamide ($C_{14}H_3(NO_4)_2NO_2$), obtained on boiling chrysammic acid with solution of ammonia:

The solution, on cooling, deposits the substance in acicular crystals, reddish-brown by transmitted light, and having a green metallic lustre by reflected light.

Chrysamidic acid ($C_{14}H_5(NO_4)_2NO_4$) is formed when chrysammic acid is boiled with dilute hydrochloric or sulphuric acids,

It crystallises, on the cooling of the solution, in needles that, when dry, have a deep olive-green colour. It forms salts with bases that resemble the chrysammates, but which may be distinguished from them by yielding ammonia when gently warmed with solution of potash.

Hydrochrysamide ($C_{14}H_6(NO_4)NO_2$) results on boiling chrysammic acid with solution of sulphide of potassium containing excess of caustic potash. It crystallises on cooling under the form of beautifully-coloured needles.

CHRYSANILIC ACID. [INDIGO.]

CHRYSANISIC ACID. ($C_{14}H_5(NO_4)_3O_5$) An acid obtained by boiling nitranisic acid with fuming nitric acid. It crystallises in small scales of a magnificent gold colour. It is insoluble in water, but soluble in hot alcohol and ether. It is a monobasic acid, and forms an extensive series of salts termed *chrysanisalts*. It may be regarded as picric acid, in which one equivalent of hydrogen has been replaced by the compound radical methyl, thus:—

CHRYSA'NTHEMUM, a name applied to a genus of composite flowers, most of which are wild in different parts of Europe, and of little general interest; it is however popularly known from its also

comprehending the *Chrysanthemum Sinense*, a Chinese half-shrubby plant, whose numerous varieties constitute one of the chief ornaments of gardens in the months of October, November, and December.

The native state of this species is not certainly known, all the many varieties now in gardens having been bought in the markets of Macao, from the Chinese traders. [CHRYSA'NTHEMUM, NAT. HIST. DIV.] In the cultivated state the plant has bluish-green broad leaves with sharp serratures and deep lacerations; and the flower-heads consist exclusively of ligulate florets of almost every colour, except blue. Pure white, bright yellow, deep and pale red, rich purple, and a dark more or less brown, occur in different varieties of this favourite flower, and together contribute to the beauty for which the species is so much admired. It is probable that the numerous varieties cultivated by the Chinese, and now introduced to Europe, have been the result of ages of careful improvement, and that their properties have been derived partly from mere sporting and partly from intermixture with allied species unknown in Europe; for among those now cultivated are varieties remarkably different in constitution, many being capable of bringing their beautiful flowers to perfection in the open air, and thriving well even in the confined spaces and corrupted air of large towns, while others hardly unfold them even beneath the atmosphere of a green-house or stove. They all strike root with great facility by cuttings, which should be taken from the parent plant at midsummer, and planted in a cool frame under a bell-glass. After rooting they may be successively transferred from one sized pot to another, until they have formed two or three stout stems ready for flowering, when they must be finally left at rest. If the soil in which they grow is rich, and the air cool and moderately moist, with a free exposure to light, cuttings struck at midsummer will flower beautifully in the succeeding autumn. The size and perfection of their flowers is increased by about half of the flowerheads that naturally appear being destroyed. As the varieties of this plant are very numerous, and very different in their degrees of hardiness and beauty, it will be necessary for the grower to ascertain the nature of the varieties he is about to cultivate.

The varieties of the hardy class may be cultivated without any protection by having their stems pegged down upon the surface of the earth, so as not to be allowed to rise more than a few inches above it when in flower. So treated they form a charming ornament of a flower-garden; but the other kinds do not like this treatment.

Seeds of these plants have been obtained at Oxford and in Jersey, and many new varieties have been raised, among which are some that rival the handsomest of the Chinese sorts.

CHRYSATIC ACID. [CHRYSAMMIC ACID.]

CHRYSEN ($C_{12}H_3$) is one of the numerous compounds formed in coal tar. It is a yellow crystalline solid, melting at a temperature of 455°.

CHRYSOLEPIC ACID. [CARBAZOTIC ACID.]

CHRYSOPHANIC ACID. ($C_{20}H_8O_6$?) *Rhubarbaric Acid*, *Rhubarbarin*, *Rhein*, *Rheic Acid*, *Rheumin*, *Rhaponticin*, *Rumicin*, is found in the *Parmelia parietina*. It occurs in the form of golden yellow crystals, and with solutions of potash and ammonia, in alcohol, yields a beautiful red colour.

CHRYSORHAMNIN ($C_{28}H_{11}O_{11}$), the yellow colouring matter of Persian berries—the fruit of the *Rhamnus amygdalinus*. It crystallises in beautiful golden yellow stellar groups. By solution in water or in alcohol it is decomposed, and converted in *xanthorhamnin* ($C_{28}H_{12}O_{14}$). It is soluble in ether without decomposition, and is deposited again on evaporation of the solution.

CHURCH, or **KIRK**, which is precisely the same word in a varied orthography, is supposed to be the Greek word *κυριακός* (*kuriakos*), a derivative of *κύριος* (*lord*), one of the designations of Jesus Christ, the founder of the Christian system. It is one of the Saxon adoptions from the Greek. *Kuriakos* is an adjective, and we must understand after it some word denoting flock, or house, the Lord's flock, the Lord's house; the two senses in which kirk, or church, is used.

Of church, as denoting an edifice appropriated to Christian purposes, we treat in a separate article. We have now to speak of it as a term used to designate bodies or communities of men, when contemplated under the aspect of being persons who are followers of the Lord Jesus Christ. We shall endeavour to exhibit and illustrate the various senses in which it is used with as much completeness as our limits will allow. The word church has been used from the most remote period to represent the Greek term *ἐκκλησία* (*ecclesia*), which often occurs in the New Testament, which was adopted into the Latin language without any change, and which gives us our words ecclesiastics and ecclesiastical, which correspond to the Saxon terms churchmen, and of churchmen. The meaning of the word *ecclesia* among the classical Greek writers is "meeting or assembly," and in this or the somewhat modified sense of "community" it was adopted by the writers of the New Testament.

The whole community of Christians thus constitute the church. This is the sense in which the word is most commonly used in the New Testament: as when it is said that "the Lord added daily to the church such as should be saved" (Acts ii. 47); "Head over all things to his church" (Eph. i. 22); "concerning zeal, persecuting the church" (Phil. iii. 6); and when our Lord said, "Thou art Peter, and on this rock I will build my church" (Mat. xvi. 18), he contemplated that

majestic assembly, the multitude whom no man can number, who in ages to come should form the great Christian community. And as, when thus used by the Apostles, it comprehended all the disciples of Christ, without regard to questions which divided the opinions of Christians even in the earliest times, so it is still often used to denote the whole body of Christians, notwithstanding any peculiarities in their church order and ritual, or however they may understand the instructions on some points of Christ and the Apostles.

But it soon came to be regarded as essential to the idea of a church that the believers should be bound together by a species of mutual pledge, and form a compact and united body. Certain outward forms of profession came to be regarded as requisite for every member, such as baptism and partaking in the Lord's Supper; certain officers, as bishops, pastors, and deacons, were regarded as essential; as well as certain uniform services, and the acknowledgment of certain propositions as containing a just exposition and summary of the doctrine of Christ and the Apostles. A continued effort seems to have been making from a very early period in the history of Christianity to bring the body of professing Christians into this state of consistency and uniformity. And to give the greater effect to the effort, the bishop of Rome, who was represented as the direct successor of St. Peter, the rock on whom the church was to be built, received by almost universal consent a kind of headship, or supremacy, and about him was gathered a council, consisting of other bishops, pastors, and deacons, forming a supreme authority in this compact community, and a court of ultimate appeal. Up to the time of Constantine, the church had been independent of the State. By uniting the two, the church acquired rank and wealth—the state the means of influencing its rulers. Nearly the whole body of professing Christians in the states of western Europe were, by various means, brought to enrol themselves in this great confederacy, and they formed for many ages the church, a numerous and in the main a well-ordered and well-governed community. But the removal of the seat of empire led indirectly to the first great separation into the eastern and western churches, continuing to the present day under the forms of the Greek church and the Roman Catholic church.

At the Reformation, certain states of Europe separated themselves from the Western Church. The separation was made on various grounds: objections to the tyranny of the ecclesiastical authorities: to their exactions; to their assumption of powers not sanctioned by reason or Scripture; to the corrupt lives of some of the persons near the head of the church; together with an opinion that the ceremonies enjoined in the ritual were superstitious, if not idolatrous; and that many things were taught to the people as Christian verities which not only had no countenance from Scripture, but which were opposed to the plain teachings of Christ and his Apostles. Many of the leading reformers did not look to the disruption of the church, but to the reformation of it in doctrine and discipline, leaving the community of believers in the compact order in which they found them. But the resistance which was made to the efforts of the reformers, combined with other things, rendered this impracticable, and nothing remained for the states in which the call for reformation was the loudest, and where a strong sense of the corruption of the Roman Catholic system had possessed the minds both of rulers and people, but to break off from the great confederacy, and to renounce entirely all connection with and all spiritual allegiance to the pope, the great head of the church. Hence arose another use and application of this term *church*, and we hear of the Lutheran church, the church of Geneva, the church of Scotland, and the church of England, meaning the Christian members of those political confederacies, or belonging to those nations, when regarded under the aspect of being professed believers in Christ.

The expediency and the right of particular nations thus to detach themselves from the great community of Christians, and to establish churches of their own, have been subject of controversy. Protestants, or Reformers, however, regard the point as settled, and in all the Protestant states of Europe, there are *national churches* established, founded on the public law, and regulated by the same public will which regulates affairs purely political and secular. Those national churches of Protestantism vary among themselves on numerous points of order, ritual, and doctrine, according to the peculiar opinions of the persons who happened to possess the chief influence at the time when the new faith, form, and order were established, or who at a somewhat later period had influence sufficient to modify the church in any of these points. Hence there is no common church of Protestants. Each Protestant nation has its own church, and regulates its own spiritual affairs without communication with other Protestant people. It is a system of national independency. These national churches, however, are not found to comprehend all persons who in their political character are members of the respective nations. There are many who separate themselves from the national union because they object to the principle of a national church. They contend that there should be no such church regulated by councils and parliaments, but that the believers in Christ should be left at entire liberty, each person for himself to connect himself with others, if he sees proper to do so, and thus to form Christian communities on principles and for purposes such as each individual might approve for himself. The Congregationalists or Independents of England, the most numerous class of English dissenters, in the declaration of their faith,

church order, and discipline, issued by authority in 1833, avow the principle that each society of believers associated together for religious purposes is properly a Christian church. The question about which there has been so much disputation, of the union of church and state, is in effect, and when stripped of its abstraction and its personification, nothing more than the question whether there shall be a union of the people of each nation in one Christian society, the affairs of which are regulated by the national will as that will is collected on other subjects; or, whether there shall be no expression of a common will, but each person be left to receive or neglect Christianity, and to make his public profession of it in whatever way seems to him to be the best. Our limits do not allow us to enter into the discussion of this question, but we may state the main arguments briefly thus: In behalf of a national church it is contended that without some public provision there would soon be many parts of the country without Christian ministrations at all; that by securing an order of well-instructed ministers, there is the best preservative that can be devised against the prevalence of injurious superstition and dangerous errors; that affairs of such importance as these should be subjected to the consideration and direction of the enlightened mind of a people; and that practically from the moment that property is acquired by any body of professing Christians, that body must become amenable to the state, must apply to the state for direction whenever questions arise respecting it, so that it is in fact impossible entirely to disjoin affairs of religion from affairs of state. On the other hand, it is contended that to set up articles of faith and forms of worship is an injurious invasion of the rights of Christians; that to connect the profession of particular opinions with temporal advantages is unfavourable to the progress of inquiry and of truth, and has a tendency to produce simulation in Christian ministers; that the system leads to political subserviency, and fosters a worldliness of spirit; and that practically the system is not acceptable to the nation, as is evinced by the number of persons who, notwithstanding the losses and inconveniences to which, in consequence, they subject themselves, yet do not belong to the church.

The Methodists do not, we believe, speak of themselves as a church; but their system is in all its great features that of a Presbyterian church.

We have now gone through the principal senses in which this term *church* is used when it is applied with any propriety. But we cannot conclude without noticing one other sense in which the word is often used, and we notice it to condemn it as mischievous, and in every point of view incorrect and improper. We mean when *church* is used to denote the officers of the church, the bishops, priests, and deacons; a use of it neither sanctioned by etymology nor the usage of primitive times, and which is calculated greatly to mislead, as things which are predicated, and truly predicated, of the church in its proper sense of a community of believers in church order, and appointed with proper church officers, may be transferred inadvertently to *church* when it is the officers only who are meant. "The interests of the church," for instance, a very common phrase, are properly the interests of the great English community looked upon in the aspect of its relation to Christianity, not the interests of the officers or ministers only. Their proper designation is not the church, but the clergy.

CHURCH. An ecclesiastical edifice, sometimes built after the model of a modern basilica, sometimes in the form either of a Latin or a Greek cross, and sometimes, though much more rarely, circular in form. The basilica form however must be considered as belonging to the churches of the early Christians [BASILICA]; cruciform churches are of Romanesque date, and were almost universal during the prevalence of Gothic architecture. The origin of the difference between the form of the Latin and Greek cross belongs to the period of the division between the Eastern and the Western churches. [BYZANTINE ARCHITECTURE.] The Latin cross was in common use in the greater part of Europe until the Reformation. Some resemblance to the basilica form may be traced in modern churches erected since the Reformation to the revival of Gothic architecture.

A church or cathedral with a Greek cross has the transept as long as the nave and choir: the greater part of the Greek churches are built in this form. The Latin cross has the nave much longer than the transept and choir. The greater part of our older parish churches consist of a nave with aisles, a chancel (in the larger churches, a transept), and a tower sometimes at the intersection of the arms of the cross, but usually at the western end. Many of our modern churches, and particularly those constructed in the 18th, and early part of the 19th century, consist of only one long nave, with an altar at the east end; the cross form, or transept, is in some instances scarcely perceptible, and in others entirely omitted. In the nave of the church, towards the east end, are placed the pulpit and reading-desk, now almost invariably on one side, but during the prevalence of a semi-classic style often in the centre of the nave. The altar end of the church is raised by a step or steps, and is enclosed. The font is sometimes placed near the entrance, at others nearer the altar. Stoups, or small stone basins, set in niches and intended for holy water, were general in English churches before the Reformation, and are still often seen in village churches. Near the altar in ancient churches there are sometimes sedilia, or niches, with seats in them, raised each a step above the other. According to some ecclesiological writers the correct division of a church is into nave, chancel, and sacarium.

Churches are of five classes, metropolitan, cathedral, collegiate, conventual, and parish churches. The term cathedral is derived from *καθέδρα*, 'a seat,' from the seat or throne of the bishop being placed therein. Cathedrals are the chief ecclesiastical structures of the dioceses in which they are situated.

Almost every cathedral is varied in plan, although the leading features, the nave and choir, are found in almost all. The plan usually consists of a galilee, or chapel, at the principal entrance; the nave or

main body of the church; the side aisles, which do not rise so high as the nave, and are placed on each side of the nave, sometimes with chapels, at other times without, between the openings formed by the windows; the choir, or place for the ceremonies of the church; the transept, or division at right angles to the end of the nave next the choir, which projects on each side, and forms a cross on the plan. Some cathedrals have a double transept, and the transepts have often aisles. At the end of the choir is the high altar, behind which is

Plan of Durham Cathedral.

usually a lady chapel, or chapel to the Virgin. The choir end of a cathedral is sometimes terminated by an apsis, or semicircular end. Along the sides of the choir are ranged richly carved seats, ornamented with arches, pinnacles, and tracery, carved in oak. The bishop's seat, richer than the others and raised above them, is on one side, at the eastern end. The choir has also side aisles. Cloisters and a chapter-house are usually attached to English cathedrals, but the latter are more rarely met with on the Continent, the chapters being usually held in the cathedral, or in a chapel within the cathedral or abbey. The minor parts of a cathedral are the muniment room, the library, the consistory court, the vestries of the dean and chapter, minstrels' chapels, a font, and a minstrels' gallery.

Beneath the body of the cathedral there is usually a crypt, or low basement, supported on arches springing from thick columns, as in Canterbury Cathedral and others. Both externally and internally the ancient cathedrals of England, France, and Germany display all the

magnificence of Gothic architecture. Like ecclesiastical buildings generally, they stand with the altar towards the east, and the principal entrance to the west; the transept is placed north and south. At the point of intersection of the transept with the nave there is usually a lofty tower, sometimes surmounted by an elegant spire, as in Salisbury Cathedral. Sometimes the principal or western front has a tower at each angle, and these in some instances are also terminated with spires. The nave of a Gothic cathedral is supported by clustered columns, arched from one to the other, over which there is usually a row of small arches forming a gallery, which is called the *triforium*, and above are windows called clerestory windows. The aisles are lighted by windows placed between the openings of the arches of the nave; and, externally, the buttresses of the aisles often rise, supported on an arch, to the wall of the nave: these are called flying buttresses. The exterior walls of the cathedral, with its towers, are generally decorated with buttresses, surmounted with pinnacles; and between the but-

tresses are the openings or windows of the nave and aisles. The ceiling of the nave is sometimes of stone, and covered with tracery formed by the intersection of the arches which spring from the clustered columns of the nave. The west or principal front is usually the most highly decorated with tracery, pinnacles, and sculptured

figures. In the side aisles, and the aisles of the choir, there are often chapels richly designed, which contain the tombs of the founder, &c. Our cathedrals abound with monuments of various epochs, from the early Norman period of our history to the present time. The chapter-house and cloister are large and important features in many of our

Chapter-house, Salisbury.

cathedrals. The finest chapter-houses in England are of a polygonal form on the plan, with a seat running round from the entrance, and the interior decorated with sculpture, and in some instances with painting. In some chapter-houses a column, or cluster of columns, rises from the centre of the room, from which spring the sides of pointed arches, meeting the other halves of pointed arches rising from the column or columns at the angles of the walls.

The chapter-house of Salisbury Cathedral contains some of the finest specimens of the kind of sculpture usually found in such buildings.

The cloisters are rectangular enclosures, with a richly ornamented and arched gallery running round the sides, and a wall forming the back of the enclosure. The arches, which are filled with tracery, look into an area, where probably the monks were formerly buried. There are also cloisters in some of the colleges of Oxford and Cambridge. The cloisters seems to be very similar to, and perhaps derived from, the crypto-porticus of antiquity. [CHALCIDICUM.] This part of the ecclesiastical structure may have been used not only for exercise, but for study. In England the cloisters were probably glazed; in Italy they are often decorated with frescoes, by celebrated masters. Chantries, or chapels for singing mass, were formerly founded by the pious for the benefit of their souls. [CHANTRY.] They are often placed between the pillars of the nave, as the chantry of Cardinal Beaufort at Winchester; the effigy was also placed within the chantry. Some are complete chambers formed in the aisle of the choir, as at Ely; and others are independent of the cathedral, as at Westminster. In Byzantine churches [BYZANTINE ARCHITECTURE], and in some modern cathedrals and large churches, the principal feature is a dome, as Sta. Sophia, at Constantinople, St. Mark's at Venice, Santa Maria de' Fiori at Florence, St. Peter's at Rome, St. Paul's, London, the Pantheon at Paris, and many others.

Some parish churches have very much the form of a cathedral, as Christ church, Hants. The chancel of a church, which is sometimes the property of a layman, corresponds in situation to the choir of a cathedral, and, like it, is railed off from the body or nave of the church. [CHANCEL.] The chancels of our churches often contain the monuments of individuals connected with English history and literature, as at Arundel church, and Stratford-upon-Avon. In parish churches, however, the great tower is seldom placed at the intersection of the nave and transept, but forms the entrance at the west end, and contains the belfry.

The ancient cathedrals of England are Canterbury, Carlisle, Bristol, Chichester, Chester, Durham, Ely, Exeter, Gloucester, Hereford,

Lichfield, Lincoln, Norwich, Oxford, Peterborough, Rochester, Salisbury, Wells, Winchester, Worcester, and York. St. Paul's, London, is modern. Besides these there are several edifices, called minsters, which possess a cathedral character both in their construction and in their uses, as Westminster, Beverley-minster, and Lichfield and York cathedrals, which still retain the name of minster. Abbey churches had also a cathedral character.

The cathedrals of Norwich, Westminster, Canterbury, Peterborough, and Gloucester, have a semicircular apsis.

Canterbury, which dates from shortly after the Norman conquest, was built on the site of an earlier cathedral, but on the model of that of St. Stephen at Caen, but was subsequently, at different times, greatly enlarged and altered. It has a nave of the decorated style, and a cloister on the north side leading to the chapter-house, which is in the form of a parallelogram; double transepts, choir, and side chapels. At the end of the choir is an elegant chapel, with an apsis, and a circular chapel beyond, called Becket's Crown. The font is in a circular chapel, leading from the north transept. To this building is attached a library. The crypts underneath the entire cathedral are the finest in the kingdom. There are three towers, one in the centre, and two at the west end. The north-western tower was of Norman date, but was replaced by a new one in 1832. The grand central tower was not commenced till towards the end of the 15th century.

Ely has a centre tower and lantern 170 feet high, and a fine tower at the western entrance, 215 feet high; it had two towers at the angles of the western entrance, but only one remains. The style of the building externally is Norman and Early English, or First Pointed. The nave, which is 72 feet high, and 75 feet wide, is a beautiful specimen of the Norman style, the elevation consisting of three tiers of arches, with long clustered shafts round each pier. The elevation of the choir internally presents a superb design of decorated English. It was erected, with the equally beautiful chapel of St. Mary between the years 1321 and 1349. The tower and lantern, supported on eight large piers, are unique among English Gothic churches. Ely lantern is said to have suggested to Sir C. Wren the idea of the lantern over the dome of St. Paul's. This cathedral has the lady chapel at one side, and not at the east end.

Salisbury is in many respects one of the finest English cathedrals, and the most uniform in style, having been commenced in 1220, and virtually finished about 1258: it is, therefore, a pure example of the First Pointed or Early English style. It has two transepts. The lady chapel has been, perhaps injudiciously, thrown into the choir. There

is a porch entrance on the north side, leading into the nave. The cloisters, which are very extensive and magnificent, lead into a very elegantly designed chapter-house. A small muniment-room is attached to the south end of the second transept. The grand central tower is supported by four massive piers, surrounded with smaller columns; and is surmounted by a singularly beautiful spire, which attains a height of 404 feet. This spire was added some time after the tower was finished; and the weight of it has considerably warped the piers, in consequence of which the summit of the spire is near two feet out of the perpendicular.

Hereford cathedral is chiefly of Norman date (1079-1115); it has a nave, side aisles, a north porch, two transepts, a choir, a lady chapel, cloisters, and a chapter-house. The architecture of the nave is Norman. The east end is built in the early English style. Underneath the lady chapel is a crypt; and at the intersection of the nave there is a very large square tower.

Worcester cathedral has a nave and side-aisles, north porch, double transepts, choir and side-aisles, and a lady chapel. On the south are the cloisters and king's school, and a chapter-house, circular within, and polygonal on the outside, with a column in the centre, as at Lincoln and Salisbury. It is similar in plan to Hereford cathedral, having two transepts, but no side aisles to the larger transept which intersects the nave. The chapter-house and cloister are situated like those of Hereford; and at the intersection of the nave there is a handsome tower. The interior of the nave is in the Early English style. The chapter-house is Norman.

Wells cathedral, in plan, differs very much from all the rest. The chapter-house is on the north side of the church; the cloisters are in the usual place, the south, but they have only three sides; the entrance to them is from under the south-western tower of the cathedral. Here we have two western towers, a north porch, and a transept, with side-aisles; and at the end of the choir a very elegant lady chapel, with a termination at the east end, somewhat similar to the apsis of a basilica. The western front is entirely covered with sculpture of exceeding beauty. (See the excellent monograph on 'The Sculpture of the West Front of Wells Cathedral,' by C. R. Cockerell, R.A.) The architecture of the nave is Early English: the towers are much later in style. The building was commenced near the beginning of the 13th century, but not completed till 1465. There is a crypt under this cathedral.

Exeter cathedral, founded in 932, rebuilt in 1112, has a chapter-house, used as a library, in the form of a parallelogram, unlike the usual form, which is polygonal. The cloisters of this cathedral were destroyed during the Commonwealth. The singularity of the design of this edifice consists in having two Norman towers, one at the north and the other at the south end of the transept. The nave is very fine, and in the early English style. The western front is richly adorned with statuary.

Bristol cathedral, founded about 1142, is inferior to many others: it is irregular and imperfect in the plan, being without a nave; but it has one of the finest Norman gateways in the kingdom, and there is some curious Norman work in the chapter-house.

Peterborough cathedral, rebuilt 1117, is on the plan of a simple Latin cross, with one large and two small towers at the western end, terminated with spires. The altar end of the choir has the termination in the form of the ancient apsis; the lady chapel is behind the altar. The transept has side-aisles and a tower at the intersection with the nave. The west end is remarkable for three large and deeply recessed arches, which form a magnificent and extremely picturesque portico; under the centre arch is a small porch, with a library over it. The style of this cathedral is partly Norman, mixed with Early English. Some parts are of a later date, as the east end, which is in the perpendicular or latest Pointed style.

Gloucester cathedral, rebuilt 1089, differs from the preceding. The apsis is very large: attached to this part of the building, and at the entrance of the side-aisles, are chapels: the lady chapel extends backwards. The chapter-house and cloisters are on the south side. On the north side of the cloister is a projection called a lavatory. On the south side is a beautiful porch. An elegant tower, in the perpendicular style, rises from the intersection of the nave and transept. The walls and columns of the nave are Norman.

Oxford cathedral is for the most part of Norman date. It has a short nave, a choir, a north transept, with an aisle, longer than the south transept, which is without aisles. A tower and spire rise from the intersection of the nave and transepts. Two large chapels on the sides of the choir cloisters, and a rectangular chapter-house, are attached on the south side.

Carlisle cathedral, formerly a priory, is small, and inferior to the other cathedrals. The oldest part is Norman, but the most noticeable feature, architecturally, is the great eastern window, which is a very rich and elaborate example of the Early English period.

Chichester cathedral was commenced in 1082. The nave is remarkable for having five aisles, there being no other example of the kind in England. It has besides the nave and transept, a choir, lady chapel, now a library, and an irregular enclosed cloister. There is also an isolated bell-tower, like the Italian campanile in principle. This cathedral has a lofty and very elegant spire. A large proportion of the shafts of the columns are of Purbeck marble.

Chester has a nave with side-aisles, and south transept, now a parish church; a choir and lady chapel at the east end; a cloister to the north, and a rectangular chapter-house, and school-room, to the north of the cloister. The chapter-house, which is rectangular, is much older than the cathedral; the cathedral being wholly perpendicular in style, while the chapter-house is decorated.

Lichfield, partly of Early English date, has a nave and choir, nearly the same length; a lady chapel, with a semi-octangular head or apsis; an aisle on one side of the transept; and a chapter-house with parallel sides terminated at two ends with semi-octangular figures; but it is chiefly remarkable for its great central and two western towers, all of which are surmounted with spires of rich and beautiful design, and which together form a singularly picturesque group.

York is somewhat irregular in plan, from its various parts having been constructed at very different dates. Yet it has a picturesque as well as a magnificent aspect. It consists of a nave with side aisles, a choir with side aisles, a lady chapel, a transept with double aisles, an elegant octangular chapter-house leading from the north transept, a superb centre-tower, two western towers, a record-room, and a consistory-court. There is also a small crypt.

Winchester is the longest, and altogether one of the largest cathedrals in England. It is constructed on a regular plan; the cloister was rectangular, but both it and the chapter-house have been destroyed. The transept is remarkable and unique, on account of the aisles running round the three sides. A small lady chapel is attached to the east end, and there are extensive crypts under the cathedral. The west front is very fine.

Lincoln is almost wholly Early English in style, and is one of the finest of our English cathedrals. It has a nave, a choir, and double transepts. Behind the choir is a presbytery: a small galilee is attached to the south transept. The cloister, which is comparatively small, leads to a magnificent chapter-house, of a polygonal figure, ten-sided, with flying buttresses. The western transept has aisles, and a large tower at the intersection with the nave. At the west entrance there are two smaller towers. The west front is richly adorned with sculpture. Lincoln cathedral is very perfect.

Norwich is Norman in plan, and the nave, central tower, and east end are of Norman construction. The cathedral consists of a long nave, and a transept; the east end is terminated by an apsis, beyond which there is a lady chapel, and at the side of the apsis are two chapels, formed by two segments of a circle. Attached to the side-aisle of the choir is a consistory-court. There are large cloisters on the south side of the edifice. The chapter-house has been destroyed.

Westminster abbey was in the main built between 1240 and 1269, but much of it is of later date. It consists of a long nave and transept, with double aisles, an apsis at the east end of the choir, with four semipolygonal chapels round it: beyond is the sumptuous chapel built by Henry VII. In proportion to its width it is the loftiest cathedral in England. The cloisters are to the south, as well as the chapter-house, an octangular building; beyond are some smaller cloisters connected by dark passages with the great cloisters.

Rochester has a nave and side-aisles of Norman date, a double transept, but on the north side of the choir only, a choir, and a chancel at the end of it. The chapter-house is at the south-east, and in form is a long parallelogram. A low tower rises from the intersection of the transept and nave, and on the west is a chapel. It still retains its original Norman doorway, one of the richest examples of its kind existing in this country. The crypt is one of the finest remaining.

Bangor cathedral consists of a choir, nave, transept, aisles, and a quadrangular tower at the west end. The clerestory windows are circular: those below are pointed. Neither externally nor in the interior does it lay much claim to admiration.

Bath abbey, now a cathedral church, is in the form of a cross, making two small transepts without aisles; a small vestry is attached to the south transept, and a great tower rises at the intersection of the transept. The choir is the same width as the nave.

The cathedral of St. David's is partly Norman and partly of the pointed style. It consists of a nave, choir, transepts, side aisles, and a western tower.

St. Asaph's is small and plain, but not inelegant. It was built in 1284, but many alterations and additions were subsequently made. It is cruciform, with a central square embattled tower.

The numerous cathedrals of France, Italy, and Germany present beautiful specimens of architecture, not only in the Gothic, but also in the Italian style. The cathedrals of Amiens, Beauvais, Notre Dame de Paris, as well as many others, are noble examples of Gothic. Cologne, and Freiburg, in the Breisgau, are equal if not superior to any cathedral in England. St. Peter's is the largest cathedral in Europe. Vienna and Strasburg have the highest spires; the former is 465 feet, the latter 456 feet high.

CHURCH-BUILDING COMMISSIONERS were first appointed by the statute 58 Geo. III. c. 45 (which has, however, been amended by upwards of thirty subsequent acts), for building new churches in populous districts, and for dividing existing parishes, and assigning new ecclesiastical districts and determining their endowment and patronage, their recommendations being notified and carried into effect by orders in council. In this way, not only have new districts been carved out of existing parishes, and themselves considered as original parishes, but churches and chapels have in some cases been constituted the parish church, and the original parish church has become a district church or chapel of ease. The ministers of these districts are usually denominated *incumbents*, not being *parsons* and *vicars*, properly so called. The Church-Building Commission, although by the original Act limited to ten years, was from time to time extended; and the powers of the commissioners have been recently transferred to the Ecclesiastical Commissioners. (*Blackst. Comm.*, Mr. Kerr's ed., v. i. p. 398.)

CHURCH-RATES are rates raised, by resolutions of a majority of the parishioners in vestry assembled, from the parishioners and occupiers of land within a parish, for the purpose of repairing, maintaining, and restoring the body of the church and the belfry, the churchyard fence, the bells, seats, and ornaments, and of defraying the expenses attending the service of the church. The spire or tower is considered part of the church. The duty of repairing and rebuilding the chancel lies on the rector or vicar, or both together, in proportion to their benefices, where there are both in the same church. But by custom it may be left to the parishioners to repair the chancel, and in London there is a general custom to that effect.

The burden of repairing the church was anciently charged upon tithes, which were divided into three portions, one for the repair of the church, one for the poor, and one for the ministers of the church. Pope Gregory had enjoined on St. Augustine such a distribution of the voluntary offerings made to his missionary church in England; and when Christianity came to be established through the land, and parish churches generally erected, and when the payment of tithes was exacted, the tithes were ordered to be distributed on Pope Gregory's plan. Thus, one of Archbishop Ælfric's canons, made in the year 970, is as follows:—"The holy fathers have also appointed that men should give their tithes to the church of God, and the priests should come and divide them into three parts, one for the repair of the church, and the second for the poor, but the third for the ministers of God, who bear the care of that church." (Wilkins, *'Concilia,'* i. 253.) The same division of tithes was enacted by King Æthelred and his councillors in witenagemot assembled, in the year 1014. A portion of the fines paid to churches in the Anglo-Saxon time for offences committed within their jurisdictions, was also devoted to church repairs. The bishops were likewise required to contribute from their own possessions to the repair of their own churches. A decree of King Edmund and his councillors, in 940, headed "Of the repairing of churches," says that "Each bishop shall repair God's house out of what belongs to him, and shall also admonish the king to see that all God's churches be well provided, as is necessary for us all." (Schmid, *'Gesetze der Angel-Sachsen,'* i. 94.) One of King Canute's laws says, "All people shall rightly assist in repairing the church;" but in what way it is not said. There is no pretence, however, for interpreting this law of Canute's as referring to anything like church-rate. A payment to the Anglo-Saxon church, called *cyric-sceat* (church scot), has been erroneously identified with church-rate by some writers. This was a payment of the first-fruits of corn-seed every St. Martin's day (November 11), so much for every hide of land, to the church, and the laws of King

Edgar and King Canute direct all *cyric-sceat* to be paid to the old minster. (Schmid, i. 99, 165.) *Cyric-sceat* was otherwise called *cyric-amber*, *amber* being the measure of payment. (See further *'Ancient Laws and Institutions of England,'* printed under the direction of the Commissioners of Public Records, 1840.)

Churches continued to be repaired with a third of the tithes after the Norman conquest, and to as late as the middle of the 13th century. How the burden came to be shifted from the tithes to the parishioners is involved in much obscurity. The following conjectural sketch of the rise of church-rates is from a pamphlet by Lord Campbell: "Probably the burden was very gradually shifted to the parishioners, and their contributions to the expense were purely voluntary. The custom growing, it was treated as an obligation, and enforced by ecclesiastical censures. The courts of common law seem to have interposed for the protection of refractory parishioners till the statute of *Circumspecte Agatis*, 13 Ed. I., which is in the form of a letter from the king to his common law judges, desiring them to use themselves circumspectly in all matters concerning the bishop of Norwich and his clergy, not punishing them if they held plea in court Christian of such things as are merely spiritual, as '*si praelatus puniat pro cimeterio non clauso, ecclesia discooperta vel non decenter ornata.*' Lord Coke observes, 'that some have said that this was not a statute, but made by the prelates themselves, yet that it is an act of parliament.' In the printed rolls of parliament, 25 Ed. III., No. 62, it is called an ordinance; but in the statute 2 & 3 Ed. VI. c. 13, § 51, it is expressly styled a statute, and it must now clearly be taken to be the act of the whole legislature. From the year 1285, therefore, the bishops were authorised to compel the parishioners by ecclesiastical censures to repair and provide ornaments for the church." (Sir John (now Lord) Campbell's *'Letter to Lord Stanley on the Law of Church-Rates,'* 1837.) But for long after the existence of the custom of making the parishioners contribute to the repairs of the church, and after the statute *Circumspecte Agatis*, the original obligation on the clergyman to repair out of the tithes was remembered. Lord Campbell quotes in the same pamphlet a passage from a MS. treatise in the Harleian collection, written in the reign of Henry VII. by Edward Dudley, a privy councillor of that king, which thus lays down the law for appropriation of the incomes of the clergy: "One part thereof for their own living in good household hospitality; the second in deeds of charity and alms to the poor folk, and specially within their dioceses and cures, where they have their living; and the third part thereof for the repairing and building of their churches and mansions." Lyndwode, who wrote in the 15th century, says, that by the common law the burden of repairing the church is on the rector, and not on the laity. "But certainly," he adds, "by custom even the lay parishioners are compelled to this sort of repair; so that the lay people is compelled to observe this laudable custom." (*'Const. Legatin.'* 113.)

It may now be assumed as undoubted, that by the common law of this country the inhabitants of a parish are bound to bear the expense of keeping the parish church in repair; and the mode in which this obligation is performed is, in practice, by church-rates imposed by the parishioners themselves, at a meeting summoned by the churchwardens for that purpose. Upon the churchwardens, conjointly with the minister, devolve the care of the fabric of the church, and the due administration of its offices. With a view to provide a fund for such expenses, it is the duty of the churchwardens to summon parish meetings for the purpose of levying rates; and if they neglect to do so they may be proceeded against criminally in the ecclesiastical courts. A mandamus also is grantable to compel the churchwardens to call a meeting. They may also be punished by the ecclesiastical courts for neglecting to make repairs for which money has been provided by the parish; but if they have no funds in hand, and if they have not failed to call the parishioners together, they cannot be punished. If the parish fail to meet, the churchwardens then constitute the meeting, and may alone impose a rate; but if the parish should assemble, it rests with the parishioners themselves to determine whether they will make a rate; for a valid rate can only be made by an actual or constructive majority of the parishioners in vestry assembled, and if the majority should refuse to make a rate, the minority cannot make it. (*Gosling v. Veley*, 4 House of Lords Cases, p. 679.)

The repair of the parish church, and the provision of the necessities for divine service, are thus, to a great extent, at the option of the majority of the parishioners assembled. Before the Reformation, the parishioners could be punished in the ecclesiastical court for failing to repair the parish church; and the punishment was, to place the parish under an interdict, or sentence of excommunication, by which the church was shut up, the administration of the sacraments suspended, and any parishioner who died was buried without bell, book, or candle, and the sentence of excommunication and interdict may still be obtained in the ecclesiastical courts. But there are now no means of compelling the parishioners to provide church-rates. There is no remedy by mandamus: the Court of Queen's Bench will grant a mandamus, as has been already said, directing churchwardens to call a parish meeting, but not to compel parishioners to make a rate. The ecclesiastical courts cannot make a rate, nor appoint commissioners to make one.

The existing poor-rate of the parish is generally taken as the criterion for the imposition of the church-rate; but decisions as to poor-

rates are not binding in case of church-rates, and the proper test for church-rates is a valuation by competent judges, grounded on the rent the tenant would be willing to pay for the premises. All property in the parish is liable except the glebe-land of that parish, and the possessions of the crown when in the actual occupation of the crown, and places of public worship. Stock in trade is not generally rated for church repairs, but a custom may exist rendering it rateable in a particular parish. A ratepayer cannot, by an original proceeding in the ecclesiastical courts, raise objections to a rate for the purpose of quashing it altogether. If he wishes to dispute it, he ought to attend at the vestry, and there state his objections; if they are not removed, he may enter a caveat against the confirmation of the rate, or refuse to pay his assessment. In the latter case, if proceeded against in the ecclesiastical court, he may in his defence show either that the rate is generally invalid, or that he is unfairly assessed. The consequence of entering a caveat is an appeal to the ecclesiastical judge, who will see that right is done.

A retrospective church-rate, or rate for expenses previously incurred, is bad. This has been often decided in the courts of common law and equity, and in the ecclesiastical courts. The reason is stated by Lord Ellenborough in the judgment of the court in *Rex v. Haworth* (12 East, 556):—"The regular way is for the churchwardens to raise the money beforehand by a rate made in the regular form for the repairs of the church, in order that the money may be paid by the existing inhabitants at the time, on whom the burden ought to fall."

Previously to 53 Geo. III. c. 127, the only mode of recovering church-rates from parties refusing to pay the amount of the rate, was by suit in the ecclesiastical court for subtraction of rate. By that statute, where the sum to be recovered is under 10*l.* (or in the case of Quakers, 50*l.*), and there is no question as to the validity of the rate, or the liability of the party assessed, any justice of the county where the church is situated may, on complaint of the churchwardens, inquire into the merits of the case, and order the payment. Against his decision there is an appeal to the quarter-sessions. The period of imprisonment for non-payment is limited by the 12 & 13 Vict. c. 14, to three calendar months. By several statutes, principally the 58 Geo. III. c. 45; 59 Geo. III. c. 134; and 3 Geo. IV. c. 72, Acts passed for the promotion of building churches, the common-law powers of churchwardens have been varied, and extended so as to enable them to raise money on the security of church-rates, and to apply them for the enlargement, improvement, &c. of churches, and for the building of new ones, &c.

The levying of church-rates on dissenters, who are so numerous in this country, has caused so much irritation, and the frequently successful opposition of dissenters at vestry-meetings called to impose rates has rendered church rates so precarious a resource, that various attempts have been made for the last quarter of a century to abolish them, and to substitute some more certain and less obnoxious provision for the repair of churches and the due celebration of divine worship. Although hitherto unsuccessful it is probable that no very long time will now pass without a definitive settlement of the question. There are endowments in many parishes for the repair of the church, which render church-rates unnecessary; and in many parishes arrangements have been made for voluntary subscriptions, to avoid conflicts between churchmen and dissenters, and the scandal of such disputes.

Some returns laid before Parliament in 1859, give the following particulars: annual average of amount expended during the previous seven years for church purposes, 635,881*l.* 12*s.* 4*d.* Amount, how expended—on the repair and maintenance of the church and churchyard, 336,564*l.* 12*s.* 8*d.*; for the celebration of divine worship, 173,426*l.* 6*s.* 2*d.*; for other purposes, 95,565*l.* 8*s.* 9*d.* Amount, how raised: by church-rates, 263,709*l.* 14*s.* 9*d.*; by special endowments, 48,274*l.* 17*s.* 3*d.*; by voluntary rates or subscriptions, 269,550*l.* 8*s.* 1*d.*

CHURCHWARDENS, are parish officers, who by law have a limited charge of the fabric of the parish church, of the direction and supervision of its repairs, and of the arrangement of the pews and seats. Certain other duties are imposed upon them on particular occasions. There are usually two churchwardens in each parish, but by custom there may be only one. It is said by some authorities, that by the common law the right of choosing churchwardens is in the parson and the parishioners. This is, however, by no means universally the case, as a custom prevails in many parishes for the parishioners to choose both, and in some, both are elected by a select vestry. The eighty-ninth canon of 1603 directs that "churchwardens shall be chosen yearly in Easter week, by the joint consent of the minister and parishioners if it may be; but if they cannot agree, the minister shall choose one and the parishioners another." It has, however, been questioned how far these canons are binding upon the laity, even in matters ecclesiastical.

Provision is made for the appointment of churchwardens for modern churches and chapels and new parishes, by several of the Church Building Acts.

The usual duties of churchwardens are, to take care that the churches are repaired, and for that purpose to make and levy rates; to distribute seats among the parishioners, under the control of the ordinary; to maintain order in the church during divine service; and to provide the furniture for the church, the bread and wine for the sacrament, and the books to be used by the minister in conducting

public worship. The churchwardens are by virtue of their office overseers of the poor; and they are also required to present to the bishop all things presentable by the ecclesiastical laws, which relate to the church, minister, or parishioners. In large parishes there are sometimes officers called sidesmen (*synodsmen*) or questmen, whose business it is to assist the churchwardens in inquiring into offences and making presentments. Churchwardens and sidesmen were formerly required to take an oath of office before entering upon their respective duties; but by a recent statute, 5 & 6 Will. IV. c. 62, s. 9, they make and subscribe a declaration before the ordinary, that they will faithfully and diligently perform the duties of their offices.

If churchwardens are guilty of any malversation, or refuse to account to the parishioners at the termination of their period of service, they may be proceeded against summarily before the bishop by any parishioner who is interested, or the new churchwardens may maintain an action of account against them at common law.

Under the stat. 59 Geo. III. c. 12, churchwardens and overseers are empowered to take and hold lands in trust for the parish as a corporate body; and by a decision under this act, they can also take and hold any other lands and hereditaments belonging to the parish, the profits of which are applied in aid of the church rate. (Burn's 'Ecclesiastical Law,' tit. 'Churchwardens;' Blackst. 'Comm.,' Mr. Kerr's ed., vol. i. p. 400.)

CHURN. [BUTTER.]

CICERO'NE, a name given by the Italians, especially of Naples and Rome, to the guides who show travellers the antiquities of the country. It was a common saying in Italy, when speaking of a learned or eloquent man, "é un Cicerone," "he is a Cicero;" and the poor guides and valets de place, who, generally speaking, are neither learned nor eloquent, and often make ridiculous blunders on the most trivial subjects, have now usurped the name of Cicerone. It is also the name for printing-type of a particular size.

CICISBE'O, in Italian, means a gallant, a man who courts the ladies. The term is also applied to a knot of ribands, which used to be worn appended to the hilts of swords or to the handles of fans. ('Dizionario della Crusca.') In like manner a Cicisbeo is a man who hangs upon a lady, is constantly by her side and at her beck, and attends her wherever she goes. This derogatory custom long prevailed with married ladies, especially in towns and among the fashionable classes, in Italy, but the practice is now almost entirely discontinued. The words *cavalier servente* and *patito* are also used in the same sense. The words *cicisbeo* and *cicisben* are used to express male or female coquetry.

CICUTINE. An alkaloid of unknown composition, said to exist in hemlock.

CIDER, or CYDER. A word used to signify the juice of apples expressed and fermented. The article APPLE contains a general view of the culture of apple-trees; what is here stated as to the management of apple-trees has special reference to the English cider counties.

In the Hereford district (under which name we shall refer to that county with the adjoining cider districts in Gloucestershire, Monmouthshire, and Worcestershire, while by the name of the "Devonshire district" similar portions of Dorsetshire, Somersetshire, and Cornwall, will be distinguished), where the varieties of cider-apple cultivated are far more numerous than in any other part of England, the New Foxwhelp (a seedling from the old), the Wilding, the Cherry Pearmain, the Yellow and Red Norman,* are among the many sorts that are preferred. It appears to be almost immaterial whether the crab-stocks are grafted before or within a short time after they are removed from the nursery to the orchard in which they are to stand. In Herefordshire it is usual to insert the grafts about six feet from the ground, and to plant the trees about 66 feet between the rows, and 36 between the trees where the soil is rich; if the soil is poor, less distance is allowed, as the trees will not spread with so great vigour. This seems a preferable method to that practised in Devonshire, where the grafts are inserted at from three to four feet from the ground, and the trees planted about 16 feet apart. The advantage which in Devonshire is gained from the trees being less exposed and broken by the wind, and perhaps from a greater produce of apples, is more than counterbalanced by the entire loss of the land, usually a wilderness of weeds, into which horses run in the winter, and calves in the spring, but where neither grown cattle nor the plough can ever be admitted. In the Devonshire district, the situations chosen for orchards are generally hollow dells or shelving banks, in the neighbourhood of the farm-houses, the land on which they are planted being put to little other use; while in the Herefordshire district the choice is determined chiefly by the quality of the soil, without reference to the position of the farm-house. In their youth, the trees do comparatively little injury to the land, while they receive considerable benefit from the frequent stirring by the plough of the soil round their roots, so that newly ploughed lands, or hop-yards which may be again laid down to grass as soon as the trees have acquired some strength, are spots frequently chosen. This practice is agreeable to the very sensible instruction given by Mr. Marshall ('Rural Economy of Gloucestershire'): "Plant upon a recently broken-up worn-out sward; keep the soil under a state of arable management until the trees be well grown, then lay it down

* It has been objected to Norman cider, that it will not carry to a distance without damage.

to grass, and let it remain in sward until the trees be removed and their roots decayed, when it will again require a course of arable management" (vol. ii., p. 302).

In February or March, or, where the soil is light, in October or November, holes should be dug about six feet in diameter, each being adapted in depth to the root of the tree that it is to receive. The best earth, with the turfs, if the spot is grass land, should be thrown into the bottom of the hole, and the roots of the tree separated with the hand in horizontal layers, with the richest mould between them; all the earth may then be thrown in and firmly trodden down. If the stocks are strong, the best and cheapest method of protection from the injuries of cattle is a frame of willow staves, about six feet long, cleft as those used for the bars of hurdles; these should be hammered about six inches into the ground, round the tree, and as near it as can be done without injuring the roots, perhaps three inches from it; the staves should then be nailed together with two bands of narrow iron hoops, one a foot and a half from the bottom, another at a like distance from the top, at the same time binding them round the tree as tightly as can be done without injury to the bark. Where the stocks are not strong, the best fence is "one large post, slit with a saw and placed flat-way, with the faces to the plant, and about two feet apart, with rails on each side, nailed upon the edges of the posts." (Marshall.) In the Hereford district these fences are much used; they are cheap and effectual, and from their narrowness offer little impediment to ploughing and other purposes of agriculture, which are here carried on as much in the orchards as in any other lands.

Very little attention is paid to enriching the soil round the trees when once they have been planted. In Devonshire it is common to see the weeds which are cropped in the orchards heaped near the stem, there to decay and nourish the roots; and in Herefordshire the more careful planters cause the earth to be dug once a year round trees that have been recently planted; neither is there so much care taken with the trees themselves when they have once grown strong, as the benefits which have been derived from a better system of management would warrant. In by far the largest proportion of orchards, with the exception of gathering the fruit, nothing is done to the trees from the beginning of the year to the end. To remove superfluous wood by judicious pruning (an art of which many that practise it are most mischievously ignorant), to remove part of an excessive crop of fruit, to cleanse from moss and mistletoe, which latter in frosts forms excellent food for sheep, are practices too frequently neglected.

The fruit of the different varieties of apple ripen at different times of the year, earlier or later, according to the season. Among the earliest are the Codling and American Must, which begin to fall from the trees at the end of September; and while the majority attain their maturity about the end of November or the middle of the following month, there are some from which the apples will not fall until six or eight weeks later. The customary method of picking the fruit is by striking the trees with poles, provincially called "poulting," and then gathering the fallen apples; but though this practice is almost universal, it is frequently mischievous, from the young bearing wood being broken by the violence that is used. It is better economy to pay a small extra price for collecting the fruit which falls at several times, than to injure the trees by knocking down all the fruit, the unripe as the ripe, to save a few shillings. The apples will fall by degrees, and at intervals a boy may be sent into the trees to shake the branches; in all practicable cases the use of the pole should be avoided. When the apples have been gathered, each sort by itself is collected into heaps, about ten inches deep, where they remain for a month, or more, until they become mellow; they are then ready for the mill.

Cider is manufactured with very rude machinery, by the following process: The apples are thrown into a circular stone trough, usually about 18 feet in diameter, called the *chase*, round which the *runner*, a heavy circular stone, is turned by one or sometimes two horses. When the fruit has been ground until the rind and the core are so completely reduced that a handful of "must," when squeezed, will all pass without lumps between the fingers, and the maker sees from the white spots that are in it that the pips have been broken, a square horse-hair cloth is spread under a screw-press; and some of the must is poured with pails upon the hair, the edges and corners of which are folded inwards so as to prevent its escape. Ten or twelve of these hairs are piled and filled one upon the other, and then surmounted with a frame of thick boards.* Upon this the screw is slowly worked down by a lever; and with the pressure, a thick brown juice exudes from the hairs, leaving within them only a dry residue, which, in years when apples are scarce, is sometimes mixed with water, ground again, and the liquid pressed out as before. This latter product is called "water cider," a thin unpalatable liquor, which is given to the labourers early in the year.

The cider is received by a channel in the frame of the press upon which the hairs stand, emptying into a flat tub called a "trin." From the trin it is poured with buckets or "racking cans" into casks, placed either out of doors or in sheds where there is a free current of air. In

* This is the process in the Hereford district. In Devonshire a lever press is used, and "reed," unthrashed straw, is placed in layers in the place of hairs. The method used in the south of France for expressing oil from olives is identically the same.

about three or four days, more or less according to the heat of the weather, the liquor usually will ferment; the thick heavier parts will subside as a sediment at the bottom of the cask, and the lighter become bright clear cider. This should then be "racked" or drawn off into another cask, and the sediment be put to strain through linen bags, and what oozes from them should be restored.

It is during the fermentation that the management of cider is least understood, and there is the greatest hazard of injury. It is necessary also to know what fruit will by itself make good cider, which kinds should be ground together, and what proportions should be mixed. But it is in preservation of the strength and flavour after the cider is ground that the principal difficulty consists: *slight* fermentation will leave the liquor thick and unpalatable; *rapid* fermentation will impair both its strength and durability; *excessive* fermentation will make it sour, harsh, and thin. Other things being equal, that cider will probably prove the best in which the vinous fermentation has proceeded slowly, and has not been confounded with the acetous. The remedies used in cases of cider not clearing are either yeast or the addition of cider in a state of fermentation, isinglass, eggs, or a quart of fresh blood stirred up with the liquor, in which last case it is to be racked on the following day; these do not always prove effectual. But the common evils are excess or rapidity of fermentation; and if a better quality than farm-house or "family drink" is sought, cider requires so much care to prevent its being spoiled, that the best and most careful makers frequently have it looked at during each night for some weeks after it is made; and if the bubbling, hissing noise, the sign of fermentation, becomes frequent or too loud, the liquor is *immediately* racked off into another cask: this check often requires to be repeated several times; but although at each racking some portion of the strength will be lost, the body, flavour, and sweetness will chiefly be retained. It is not the habit of the farmer to add sugar, treacle, brandy, or any colouring matter to the liquor; it is only adulterated in the hands of cider dealers and publicans, who will not lose a hogshead, and if one has turned sour, or has been otherwise damaged, it must be "doctored," in order to render it marketable.

At the beginning of January the cider is moved into cellars, where by large growers it is frequently stored in casks of great capacity, containing 1000, 1500, or even 2000 gallons; these are cheaper in proportion than smaller vessels, and are thought to preserve the cider better. In March the liquor is bunged down; it is then fit for sale, and may be used soon afterwards, though it will greatly improve by keeping. If bottled cider is required, it should be bottled and wired in the September or October after it is made; some persons prefer an earlier time, the end of April or the beginning of May; a greater degree of effervescence is thus attained, but a considerable loss accrues from the number of bottles that will burst.

In 1830 the tax upon cider of 10s. a barrel was taken off (M'Culloch, 'Dic. Com.'). and in the same year an Act was passed allowing any person to sell cider upon the payment of 2l. 2s. annually for a licence from the Excise. This Act was amended in 1834, and a licence for the sale of cider is now granted by the Excise to an application signed by six ratepayers of the applicant's parish, the payment being 3l. 3s. if the liquor is to be drunk on the premises, 1l. 1s. if it is not. These alterations have necessarily added greatly to the consumption; but the increase of orchards, and productive seasons, have fully supplied the demand. At present, the price in the hands of the grower may be thus estimated: Of the best cider, from 1s. to 1s. 6d. per gallon; good, from 8d. to 1s. per gallon; family cider, used by farmers and in public-houses, from 4d. to 10d. per gallon; 'drink' for labourers, from 2½d. to 6d. per gallon. These prices amply remunerate the farmer, who, in many instances, might increase his profits by a diminution of the cost of production. It cannot certainly be supposed that small growers can go to the expense of procuring much machinery; nevertheless, the extreme clumsiness of the present wasteful system would fully warrant larger owners in erecting suitable buildings and apparatus. It is true that some improvements have been made, that larger mills are used, that in the press an easily worked iron screw has been substituted for an awkward wooden one; but far more remains to be effected. If the mill was placed upon a first floor, which could easily be done in a building erected against a bank, or having an inclined plane, so that horses might enter at that height, all lifting of the cider from the trin might be saved, as a pipe might be carried from the press into casks in the cellar underneath. Again, if the casks in the cellars were placed upon stages, manual labour in racking might be dispensed with, and waste from spilling saved, since a pipe from a hogshead upon a high stage would empty the liquor into a cask on a lower. No use, again, is made of the syphon, a cheap instrument within the reach of any farmer's purse, which would no doubt be serviceable and economical.

The quantity consumed by workmen is very large: two or three quarts a day is the usual allowance given in Herefordshire by masters; and in harvest-time many labourers drink in a day ten or twelve quarts of a liquor that in a stranger's mouth would be mistaken for vinegar; they do not like sweet cider. Notwithstanding so great a quantity is consumed, there do not appear to be any diseases peculiar to or very general in cider countries; idiocy and rheumatism have been stated to be very prevalent in such districts; but even if this be true, cider-drinking has in no way been proved to be the cause.

Cider of good quality is made in Ireland, in the counties of Waterford and Cork; in Normandy, whence we have many of our best apples; in Belgium; and of inferior quality in Germany. It is also made in abundance, and of excellent quality, in many parts of the United States.

CIGAR MANUFACTURE. Referring to the *NATURAL HISTORY DIVISION* of the *ENGLISH CYCLOPÆDIA* for an account of the botanical characteristics of the tobacco plant, and to the article *TOBACCO* in the present division for a notice of the manufacturing and commercial relations of the trade generally, we will in this place briefly describe the production of cigars and cheroots.

The finest tobacco is rarely smoked in pipes; or, more properly speaking, the produce of Havannah and Manilla is made up into cigars and cheroots rather than into pipe-tobacco, while that of the United States is more frequently smoked in the pipe. The English dealers purchase tobacco by the hogshead, and set aside for cigars such leaves as appear best suited for that purpose. A boy, seated on a stool, takes up an unstripped leaf, folds it, strips off the stalk by a quick and dextrous movement, throws the stalk on one side, and lays the stripped leaf smoothly on a table. When a heap has thus been collected, a cigar-maker proceeds with his manipulations. He sits in front of a table, takes a leaf of tobacco, spreads it out smoothly, and cuts it into a form something like that of one of the gores or stripes in a balloon. He takes up a few fragments of tobacco-leaf, lays them on the spread leaf, and rolls them up with it into a cigar-form. He next places this cigar against a gauge or guide, and cuts it to a given length. Finally, he lays a narrow strip of leaf on the table, and rolls the cigar spirally in it, twisting one end to prevent the leaf from becoming loosened. When the cigars have thus been made, they are dried in different ways, according to the time when they are wanted for sale.

The enormous duty on imported foreign cigars (9s. per lb.), renders it expedient to import the leaf, and manufacture the cigars in England; and this branch of industry has consequently become very extensive. Nevertheless, Cuba or Havannah cigars are preferred by those who can afford to pay for them, on account of their superior flavour. Cigars are largely made in Germany, and in many other parts of the Continent; but these are not very extensively smoked in England. The imported cigars are chiefly from Havannah, Manilla, and Bengal—the last named being by far the least esteemed of the three. A few years ago, the following particulars were given of the cigar-trade at Havannah, in the island of Cuba: "The greatest manufacturers of Havannah cigars are Cabañas, Hernandez, Silva, and Rencareuil; there are a hundred others of less note, who make from 10,000 to 100,000 a day. The cigar is composed of two distinct parts, the inside and the cover. For these, two different kinds of leaves are used; of which that for the cover is generally finer in texture and more pliant [than that for the inside]. These leaves are damped the night previous to their being made up; when rolled, they are placed on a large table, where they are divided into the various qualities of first, second, third, &c., and priced accordingly. Those which are most carefully rolled are called *Regalias*, and are sold at 22 to 26 dollars per thousand; while the second best, which are of the very same tobacco, and made by the same man, only with less care, are sold at 14 dollars; and others are done so low as 6 dollars. D. Hernandez employs about fifty men in his manufactory. Of the best common cigars, a workman can make a thousand a day; of the *Regalias* six hundred. The daily issues from that immense *fabrica* are about 30,000 cigars; which at 14 dollars per thousand would give nearly 100% per day. They pay an export duty of half a dollar per thousand, and an import duty in England of nine shillings. The very best in quality do not find their way to Europe; because they are not fashionable; they are generally dark-coloured; whereas, a light-coloured and smoothly rolled cigar is preferred to the strong and highly flavoured rough ones, which are the best." Mr. M'Micking gives the following account of the great cheroot-manufactory at Manilla, in the Philippine Islands, belonging to the Spanish government. Cheroots, it may here be observed, are cigars cut off at both ends, instead of having one end pinched or screwed into a point: "In making cheroots women only are employed; the number so engaged in the factory at Manilla being generally about 4000. Besides these, a large body of men are employed in the composition of cigarettes, or small cigars, kept together by an envelope of white paper instead of tobacco; these being the kind most smoked by the natives. The flavour of Manilla cheroots is peculiar to themselves, being quite different from that of any other kind of tobacco; the greatest characteristic probably being its slight soporific tendency, which has caused many persons in the habit of using it to imagine that opium is employed in the preparatory treatment of the tobacco—which, however, is not the case. The cigars (cheroots) are made up by the hands of women in large rooms of the factory, each containing from 800 to 1000 persons. They are all seated or squatted, Indian-like, on their haunches upon the floor, around tables, at each of which there is an old woman presiding to keep the young ones in order—about a dozen of them being the complement for one table. All of them are supplied with a certain weight of tobacco, of the first, second, or third qualities used in making a cigar, and are obliged to account for a proportionate number of cheroots, the weight and size of which by these means are kept equal. As they use stones for beating out the leaves on the wooden tables, before which

they are seated, the noise produced by them is deafening, and generally sufficient to make no one desirous of protracting a visit to the place. The workers are well recompensed by the government. As very many of them earn from 6 to 10 dollars a month for their labour, and as that amount is amply sufficient to provide them with all their comforts, and to leave a large balance for their expenses in dress, &c., they are seldom very constant labourers."

Patents are occasionally taken out for novelties in cigar making; but not in any great number. A Liverpool house has purchased the use of a machine patented in America, by which cigars can be made at the rate of 5000 a day, with economy of tobacco. One of the strangest patents on this subject was obtained in 1852; it was for a method of using a hollow drill to make a hole through the cigar from end to end; drawing out the tobacco-dust from the hole by an exhausting apparatus; and lining the hole with a tube of amber or gutta percha, or varnishing the interior of the hole with liquid amber by means of a camel-hair pencil—all to make the cigar smoke more readily!

Of the extent of the cigar trade, there are no very trustworthy data; partly in consequence of the unequal degree to which cigars are included with other kinds of tobacco in the official returns. It is estimated that about 150 million cigars are annually shipped from Havannah to various countries. Great Britain imports from 2,000,000 to 3,000,000 lbs. of cigars, snuff, and manufactured tobacco annually—not one-twentieth part of the weight of *unmanufactured* leaf imported; but as the cigars are not distinguished in the tables from snuff and manufactured tobacco, the weight of the cigars alone cannot here be stated. Real foreign cigars are sometimes surreptitiously imported in such a way as to evade the duty; but more frequently deception is practised by selling cigars, made in London, or Bristol, or Liverpool, so packed, that—in the shape of the boxes, the words and symbols branded thereon, and the mode of fastening the cigars into bundles—they may present the appearance of having been imported from abroad. An enormous preponderance of the so-called Havannahs, Mexicans, Manillas, Regalias, Lopez, Cubas, Silvas, Hernandez, Principes, Frangancias, &c., sold in London, are made in the neighbourhood of Whitechapel, and have no claim whatever to the names they bear; if sold at from 12s. to 24s. per lb., they are probably made of real tobacco, of varying qualities; but the cheaper cigars and cheroots are wretched compounds of damaged tobacco, lettuce-leaves, and even brown-paper, soaked in solutions of treacle, salt, saltpetre, colouring matter, and other substances.

Besides the cigars of ordinary make, there are medicinal cigars, prepared in reference to the requirements of the healing-art. Many kinds of medicine are made up in this form. Sometimes the leaf of a medicinal plant is made up like a cheroot, and smoked by the invalid for whom the medicament is intended; or the tobacco of a common cigar is medicated by steeping in a particular liquid; or a medicated paper is wrapped round a common cigar; or the narcotic property is taken out of a tobacco-leaf before it is made up into a cigar. In one or other of these ways are made aromatised, aromatic, scented, arsenical, balsamic, belladonna, camphor, mercurial, stramonium, and other cigars. Aromatised cigars and aromatic cigarettes are made chiefly for yielding an agreeable odour, the scent-giving substance being such as tincture or bark of cascarilla, gum benzoin, storax, oil of cloves, oil of cassia, &c.; but usually, these medicated cigars are intended, by their smoke, to alleviate tooth-ache, cough, asthma, hoarseness, typhus fever, scarlet fever, &c.

CIMBRI, or KIMBRI, the name given by the Roman and Greek historians to a vast multitude of people who came from the northern parts of Germany at the same time as the Teutones, crossed the Rhine, and entered Gaul, where they joined the Ambrones, a Celtic tribe, and after ravaging and plundering part of Gaul, went into Spain, where they were repulsed by the Celtiberi. (Livy, 'Epitome,' lxxvii.) The Teutones and Ambrones then made an irruption into Italy, where they were defeated by Marius, near Vercellæ, 102 B.C. Part of the Cimbri, however, had gone into Helvetia, where they were joined by the Tigurini, a Helvetian tribe, with whom they crossed the Pennine Alps, and, after defeating the pro-consul Catulus, entered the plains of Lombardy, where they were defeated by Marius in the year after the Teutones and Ambrones, 101 B.C. From that time little or no mention is made of the Cimbri in history, but tradition says that the remnant of them settled in the central valleys of Helvetia, and the inhabitants of the Waldstätten and of the Bernese Oberland are supposed to be their descendants. Old Scandinavian words are traced in the dialect of these mountaineers. Of the original residence of the Cimbri we know nothing certain. Strabo (vii. 291-4) places them north of the Elbe beyond the Chauci, and numbers them among the German tribes. Pomponius Mela (iii. 3) places the Cimbri and Teutones in the islands of the Baltic Sea. Pliny speaks of the promontory of the Cimbri; and the peninsula of Jutland has been called Chersonesus Cimbrica, without, however, it being proved that the Cimbri ever inhabited it. Tacitus says that they "lived in the same winding tract of Germany as the Cherusicans" ('Germania'), 371. Plutarch ('Caius Marius') supposes that a great part of the force which opposed Marius were Scythians; and says they were designated as Celto-Scythians; but deems the more probable conjecture to be that they were composed of Germanic nations from the shores of the Northern Ocean. Most of the ancient writers concur in deriving them from about the

peninsula of Jutland, and in stating that they came from the north. They are, however, by some authors, represented to be Celts, and the armour and customs of the Cimbri are described by Plutarch and Strabo as very different from those of the Germans; and there is little doubt that the original invaders were joined by numerous other tribes in the course of their progress, many of whom were Teutonic. In their war with Marius, the description of their arms, and the name of their chief Bojorix, appear to designate them as Celtæ; and from the number with which they opposed Marius it is clear they could not all have come from Jutland, and if their forces had received accession from the farther north they must have been Scandinavians. But see H. Müller, 'Die Deutschen,' and Latham, Appendix to his edition of the 'Germanicus' of Tacitus.

CINCHOIDINE. [CINCHONA, ALKALOIDS OF.]

CINCHOLINE. [CINCHONA, ALKALOIDS OF.]

CINCHONA, ALKALOIDS OF. The valuable medicinal properties of *Cinchona*, or *Peruvian bark*, have long been known to be due to certain organic bases or alkaloids, but it is only within the last few years that these latter have been closely investigated, and their relations to each other pointed out. The principal ones are four in number—1, *Quinine*; 2, *Quinidine*; 3, *Cinchonine*; and 4, *Cinchonidine*. From some unimportant varieties of the bark is obtained *dricine* or *cinchovatine*. *Quinoidine* (*chinoidine*, *cinchoidine*), or *uncrystallisable quinine*, results from the action of heat and light on the other bases, and is procured both in the process of drying the bark and in the preparation of quinine, &c.; it is a variable mixture of the alkaloids with colouring matter and resin. *Quinicine*, isomeric with quinine, is produced by the action of a moderate heat on quinine or quinidine, and *cinchonine* is in like manner obtained from cinchonine or cinchonidine. Finally, *quinoline* or *cincholine* (*chinoleine*, *leucol*, *leucoline*) is a base of oily consistence formed when any of the alkaloids are distilled with caustic potash or soda.

The different kinds of cinchona bark yield very variable quantities of the several alkaloids. Not only does this arise from the bark being taken from different species of the genus *cinchona*, but trees of the same species are greatly influenced by the soil and climate in which they grow. Usually also the bark from the thick portions contains more alkaloid than that from the smaller branches of the same tree. As a general rule, however, the article known in commerce as *pale* or *gray cinchona bark*, contains a much larger proportion of cinchonine and cinchonidine than of quinine and quinidine, while the latter two predominate in the *yellow bark*. The other variety, *red bark*, mostly contains the alkaloids in about equal proportions.

A botanical description of the cinchona trees, and a lengthened consideration of the commercial varieties of the bark, will be found in CINCHONA and QUINQUINA, NAT. HIST. DIV. See also BARK, in this division.

The alkaloids do not exist in the free state in the barks, but are combined with kinic and cinchotannic acids.

1. *Quinine* ($C_{20}H_{24}N_2O_3 + n \text{ Aq.}$). Pure quinine is most conveniently prepared by adding ammonia to a solution of the neutral sulphate, collecting, washing, and drying the precipitate. It is colourless, inodorous, and extremely bitter. It fuses at about 300° , yielding when cold a yellow, translucent, friable mass, somewhat resembling common resin. Cold water dissolves 1-400th of its weight of quinine, boiling water 1-250th, cold ether 1-60th; boiling alcohol dissolves half its weight. It is also soluble in the fixed and essential oils. When an alcoholic solution is set aside to evaporate spontaneously, crystals of hydrate of quinine are obtained containing water of crystallisation. The solution of this alkaloid possesses the property of left-handed rotatory polarisation.

From the high position that quinine occupies as a medicinal agent, it has been made the subject of investigation by many eminent chemists, among whom are Pelletier and Caventou, who first isolated it in 1820, Liebig, Regnault, Laurent, Strecker, and Winckler. It is now generally admitted to be composed of—

	In 100 Parts.	
Forty equivalents of carbon	240	74.07
Twenty-four equivalents of hydrogen	24	7.41
Two equivalents of nitrogen	28	8.64
Four equivalents of oxygen	32	9.88
Equivalent	324	100.00

Quinine restores the blue colour of reddened litmus, and is very soluble in all the acids, combining with them to form neutral and acid salts. The most important are the following.

Sulphate of Quinine ($C_{20}H_{24}N_2O_3 \cdot HO \cdot SO_3 + 7 \text{ Aq.}$). This salt was formerly called the *disulphate*, a name indicating that it was composed of two equivalents of base to one of acid, but the formula of quinine having since then for good theoretical reasons been doubled, the salt has necessarily now become the neutral sulphate. It is the only compound of the cinchona alkaloids that is at present recognised in medicine. It is most economically prepared from well-pulverised yellow bark by boiling in eight or ten parts of water, containing about 12 per cent of concentrated sulphuric acid, or 25 per cent. of strong hydrochloric acid; after from one to two hours ebullition the decoction is strained off, and the residue a second and a third time boiled,

Quinine is now precipitated from the mixed liquors by adding excess of carbonate of soda or milk of lime; the precipitate collected on a filter, washed with cold water, submitted to strong pressure, and the residue digested in boiling alcohol yields a solution which usually deposits crystals of cinchonine on cooling; these having been separated, the liquid is neutralised with sulphuric acid and evaporated, when slightly coloured sulphate of quinine crystallises out, and may if necessary be obtained perfectly white by redissolving in alcohol, treating the solution with animal charcoal and recrystallising.

Another process of obtaining sulphate of quinine, which possesses the merit of obviating the use of alcohol, consists in boiling the bark in a solution of carbonate of soda, so as to extract its colouring and resinous matter, treating the residue with sulphuric acid, so as to obtain bisulphate of quinine, which is to be decomposed by carbonate of soda, and the precipitated quinine being redissolved in sulphuric acid and water, and treated with animal charcoal, the solution is to be evaporated to its crystallising point.

Sulphate of quinine thus obtained presents the appearance of colourless, light, bulky needles, which effloresce when exposed to the air; one part requires for solution about 740 parts of cold, or 30 of boiling water, 80 of cold alcohol of sp. gr. 0.850, and much less of boiling alcohol. When heated, sulphate of quinine becomes luminous, fuses, and on cooling has the appearance of melted wax; it afterwards reddens, begins to decompose, and when the heat is raised to ignition in the air, charcoal is obtained, and this, if the salt is pure, is eventually entirely dissipated without residue. It is one of the remarkable properties of this salt to give a blue tinge to water, producing the phenomenon of *fluorescence*. This salt is composed of—

One equivalent of sulphuric acid	40 or 9.17
One equivalent of quinine	324 „ 74.31
Eight equivalents of water	72 „ 16.52
Equivalent	436 100.00

Bisulphate of quinine ($C_{20}H_{24}N_2O_3 \cdot 2SO_3 \cdot 2HO + 14 \text{ Aq.}$) is prepared by adding sulphuric acid to a solution of the neutral sulphate. By evaporation it is obtained in rectangular prisms. It effloresces when exposed to the air, is soluble in eleven times its weight of water at 55° , and in eight times at 72° ; it is also dissolved by alcohol. At 212° it fuses in its water of crystallisation. Though neutral in composition, it is acid to litmus paper, but not sour to the taste. By the action of heat in the air it is totally decomposed and dissipated.

Nitrate of quinine ($C_{20}H_{24}N_2O_3 \cdot HO \cdot NO_3$). Formed by double decomposition of solutions of sulphate of quinine and nitrate of baryta, or by dissolving quinine in dilute nitric acid. When the solution of this salt is evaporated to a certain point, oleaginous drops are formed, which resemble wax in appearance when they have solidified. When they are kept some days under water, they gradually alter in appearance, and are converted into groups of regular, brilliant crystals, and it often happens that one drop becomes a single crystal. This phenomenon depends upon the circumstance that the salt when deposited hot is fused, and contains no water of crystallisation, but gradually combines with it to form crystals; the crystals are rectangular prisms with inclined bases, and do not possess any cleavage.

Hydrochlorate of quinine ($C_{20}H_{24}N_2O_3 \cdot HCl + 3 \text{ Aq.}$) Prepared by decomposing solution of sulphate of quinine with chloride of barium. It crystallises in silky fibres, is slightly soluble in water, and fuses below 212° .

The *bihydrochlorate* is obtained by dissolving quinine in excess of hydrochloric acid; it has a great tendency to separate into the neutral salt and free hydrochloric acid.

Chloroplatinate of quinine ($C_{20}H_{24}N_2O_3 \cdot 2(HCl, PtCl_2) + 2 \text{ Aq.}$) Precipitated when bichloride of platinum is added to quinine dissolved in slight excess of hydrochloric acid; after standing some time, the precipitate becomes of an orange colour and crystalline. It is almost insoluble in water, and quite insoluble in alcohol. This salt may be conveniently made use of in the quantitative estimation of quinine. It is not altered by drying at a temperature of 212° ; when heated to 284° , it loses two equivalents of water. Its percentage composition is—

	By Calculation.	Gerhardt.
Carbon	31.78	31.34
Hydrogen	3.71	3.98
Nitrogen	3.71	3.40
Chlorine	28.21	28.46
Platinum	26.23	26.51
Oxygen	6.36	6.31
	100.00	100.00
Water evolved at 284°	2.37	2.37

Oxalate of quinine ($C_{20}H_{24}N_2O_3 \cdot HO \cdot C_2O_3$). This salt is obtained by precipitating a soluble salt of quinine by a neutral oxalate; it is procured in the state of a white powder, which is but slightly soluble in water when cold, but more soluble in boiling water, and as the solution cools, the salt is deposited in silky crystals. It is very soluble in alcohol, especially when heated, and the salt crystallises as the solution cools. When excess of acid is added to the oxalate, it dissolves readily in water, and crystallises in needles of binoxalate.

Gallate of quinine. This salt precipitates in the state of a white powder, when a soluble gallate is added to a solution of a salt of quinine. It is soluble in hot water, but precipitates as the solution cools; it dissolves readily in excess of acid and in alcohol. This salt is produced when infusion of galls is added to infusion of yellow bark.

Kinate of quinine is the salt which exists naturally in the bark. It is crystalline, and may be obtained by spontaneous evaporation in mammellated white crusts, which sometimes consist of small needles that lose their transparency by exposure to the air, and assume a horny appearance. This salt is very bitter, slightly soluble in alcohol, but very soluble in water.

Iodoquinine is obtained by rubbing together quinine and iodine. It is a brown amorphous powder.

Bisulphate of iodoquinine ($C_{40}H_{24}N_2O_4 \cdot I_2 \cdot 2SO_3 \cdot 2HO + 10Aq.$), called *Herapathite*, after its discoverer, Herapath, is an exceedingly interesting body, on account of its optical properties. It is readily obtained by dissolving sulphate of quinine in concentrated acetic acid, and adding an alcoholic solution of iodine to the liquid heated to 130° . On cooling, large rectangular plates form on the surface, and may be removed by careful manipulation. By reflected light the crystals appear of a brilliant green colour, by transmitted light of a pale olive, while the whole of the light that passes through is perfectly polarised, so that a second plate placed at right angles on the first as completely prevent the passage of light as two plates of tourmaline, or Nicol's prisms.* [POLARISATION.]

2. *Quinidine* ($C_{40}H_{24}N_2O_4 + 4Aq.$) This alkaloid is isomeric with quinine. It is best prepared from commercial quinidine, by digesting the latter for some time in boiling ether, filtering, evaporating the solution to dryness, digesting the residue in dilute sulphuric acid, decolourising with animal charcoal, and precipitating with ammonia. A solution of the precipitate in a mixture of alcohol and ether yields, on evaporation, large oblique rhombic prisms, which are at first quite transparent, but soon effloresce and become opaque.

Heated to 320° , quinidine loses its water of crystallisation and fuses, solidifying on cooling to a resinoid mass. It is soluble in 1500 parts of cold water, 750 of boiling water, 45 of cold absolute alcohol, 3.7 parts of hot ordinary alcohol, and 90 parts of cold ether. Its solution in alcohol rotates a ray of polarised light in a contrary direction to that produced by solution of quinine.

Quinidine combines with acids, forming a class of salts somewhat similar to the corresponding salts of quinine. The *neutral hydrochlorate* contains one equivalent less of water than the quinine salt, and the *bihydrochlorate* is far more stable than the bihydrochlorate of quinine. The acetate, tartrate, and especially the oxalate, of quinidine, are much more soluble in water than the analogous compounds of quinine.

3. *Cinchonine* ($C_{40}H_{24}N_2O_2$) is produced, as before stated, in the manufacture of sulphate of quinine; or sulphate of cinchonine may be obtained from pale or gray cinchona bark, by a process similar to that for obtaining sulphate of quinine from yellow bark, and the alkaloid separated by precipitation with ammonia. It is entirely purified from quinine by taking advantage of the fact that it is less soluble in alcohol than quinine, and that its sulphate is more soluble in water than sulphate of quinine.

Cinchonine crystallises in large, brilliant, colourless prisms. It is almost insoluble in ether, slightly so in chloroform and the fixed and essential oils, and soluble in the alkalies or their bicarbonates. Heated to 329° , it fuses and solidifies to a crystalline mass on cooling. In an atmosphere from which oxygen is excluded, it may be sublimed without decomposition. Its solution in alcohol produces dextrorotation upon a ray of polarised light.

The salts of cinchonine are formed, for the most part, in the same way as the salts of quinine, than which they are more soluble both in alcohol and in water. The *bisulphate* ($C_{40}H_{24}N_2O_2 \cdot 2HO \cdot 2SO_3 + 6Aq.$) forms very large, beautiful rhombic octohedra. The *bihydrochlorate* treated with bromine forms *bromocinchonine* ($C_{40}H_{22}BrN_2O_2$).

4. *Cinchonidine* ($C_{40}H_{24}N_2O_2$) bears the same relation to cinchonine that quinidine does to quinine. It may be directly obtained from Maracáibo or Bogota barks, by processes similar to those for obtaining the other alkaloids. According to M. Pasteur, the quinidine of commerce usually contains a large quantity of cinchonidine. The latter may be detected, on examination, by the transparency of its crystals compared with those of quinidine, which rapidly become opaque on exposure to the air.

Crystallised from absolute alcohol, cinchonidine occurs in very brilliant, anhydrous, rhomboidal prisms, very slightly soluble in water or ether. The alcoholic solution turns the plane of polarisation to the left. Heated to 347° the crystals melt; and at a higher temperature, if in contact with air, burn with a smoky flame, exhaling the odour of oil of bitter almonds.

The salts of cinchonidine are obtained with equal facility to the salts of quinine, &c. They are all more soluble in water than the quinine compounds, much more soluble in alcohol, but almost insoluble in ether. The *neutral sulphate* ($C_{40}H_{24}N_2O_2 \cdot HO \cdot SO_3$) crystallises in stellate groups of silky needles.

* For details of the manufacture of large available crystals, see a paper by Dr. Herapath in the 'Pharmaceutical Journal,' vol. xiii. p. 378.

Methylic and ethylic derivatives of the cinchona alkaloids may be obtained by directly combining the several bases with the iodides of methyl and ethyl. They possess considerable theoretical interest.

Chlorine and bromine derivatives of cinchonine have also been described; but for these and other less important compounds, &c., of the cinchona bases, the reader is referred to Gerhardt's 'Traité de Chimie Organique,' tome iv. pp. 104-152.

The tests by which the cinchona alkaloids may be distinguished from each other are somewhat unsatisfactory, inasmuch as they do not admit of being readily applied. Liebig proposes for this purpose to take advantage of the difference of their solubility in ether; for instance, to detect the presence of cinchonine in the salts of quinine, 10 grains of the latter are agitated with a quarter of an ounce of washed ether and 20 drops of strong solution of ammonia; on standing, the mixture separates into two layers, the upper an ethereal solution of quinine, the lower an aqueous solution of sulphate of ammonia, on which floats any cinchonine that was present in the quinine salt. A test by which to detect even a trace of quinine or quinidine in a solution, consists in adding to it some recently prepared chlorine water, and then a few drops of ammonia, when a green coloration is produced if either of those alkaloids is present; by this method one grain may be detected in a gallon of water. Cinchonine and cinchonidine are not affected by this test. Quinine may be distinguished from quinidine by the opposite influence exerted by their solutions on plane-polarised light, the former being powerfully laevogyrate, the latter equally dextrogyrate. Cinchonine under the same circumstances possesses dextrorotation, cinchonidine laevorotation: this test therefore, combined with the chlorine and ammonia test, presents a means, less facile it is true than could be wished, of discriminating between these four organic bases. Dr. Herapath makes use of the difference in the optical properties of the iodosulphates of the alkaloids, as a means of distinguishing them from each other.

Quinicine and cinchonine were mentioned at the commencement of this article as products of the action of heat on the cinchona alkaloids; quinine and quinidine yielding quinicine, cinchonine and cinchonidine furnishing cinchonine. The precaution necessary to be observed in the preparation of these substances, is to fuse the alkaloids at a temperature below their decomposing point. This is accomplished by mixing with a small quantity of water and sulphuric acid, and maintaining the mixture at a temperature of about 250° for three or four hours. The change that occurs is entirely molecular, the composition of the alkaloid being unaltered.

The properties of quinicine and cinchonine are, according to M. Pasteur, very similar to those of the bases from which they are obtained. They of course differ from each in chemical composition to the same extent that quinine and its isomers differ from cinchonine and its isomers, but otherwise they much resemble each other. Both are very soluble in alcohol, and nearly insoluble in water, unite readily with carbonic acid, expel ammonia from its salts, are precipitated from their solutions in the form of resinous liquids, and finally both turn the plane of polarisation to the right, though comparatively feebly. They are equally bitter, and as febrifuges possess equal merits.

Quinetine and cinchonetine are names given to the red products obtained by the action of the puce-coloured oxide of lead on boiling solutions of the acid sulphates of the alkaloids. They have not been much investigated.

Cinchovatine ($C_{40}H_{26}N_2O_8$). An alkaloid discovered by Pelletier and Corriol in *arica cinchona bark*, and called by them *aricine*. Mazzini found it in the bark of *Cinchona ovata*, and gave it the name of cinchovatine; the two are, however, identical. It is extracted in the same manner as quinine and cinchonine. Cinchovatine is insoluble in water, but dissolves in alcohol; and the solution yields large colourless inodorous prisms, which after some time have a bitter taste. It has an alkaline reaction. It melts at 370° Fahr.

The salts of cinchovatine are soluble, and crystallise very readily, especially on the cooling of saturated boiling solutions; it is soluble in ammonia, and crystallises from the solution by evaporation. The action of concentrated nitric on cinchovatine is very characteristic; it dissolves, giving an intense green colouration.

CINCHONA BARKS, *Medical Properties of.* The botanical character of some of the most important species of cinchona, as far as they were then known, as well as some of the commercial and pharmaceutical or officinal barks, have been given in NAT. HIST. DRUGS. Since then, much valuable information has been acquired, chiefly by Dr. Weddell, who spent two years in the cinchona forests of Bolivia and a part of Peru, and who has embodied the results of his researches in the splendid work, entitled 'Histoire Naturelle des Quinquinas,' Paris, 1849. To that book inquirers who demand full information must be referred, as well as to Schleiden, 'Pharmacognosie,' the contributions of Mr. J. E. Howard, to the 'Pharmaceutical Journal,' vols. xi., xii., xiv., and to the 'Description of Pavon's Specimens in the British Museum,' by Mr. J. E. Howard, of which part i., has just appeared; and chiefly to the elaborate investigations of the late Dr. Pereira, in vol. ii., part ii., p. 1605, 3rd ed. of his 'Elements of Materia Medica.' Lond. 1853.

It is only necessary to remark here, that Weddell divides the so-called species of cinchona of most former writers into two genera, *Chichona*, Wedd.; and *Cascarilla*, Wedd., the former comprising those species the capsule of which dehisces from the base to the apex (*Quin-*

quina of Endlicher, *Genera Plantar.*), and the latter, those which *dehisce from the apex to the base.* (*Cascarilla* of Endlicher). The only objection to this lies in the circumstance of the latter being liable to lead to confusion with a totally different bark, the produce of *Croton cascarilla* of the Bahamas. This strict definition excludes all species of *Exostemma*, *Cosmibuena*, and other plants yielding barks, useful as febrifuge medicines, but not *Cinchonas*. The practical advantage of this restriction is, that among the former only (true *cinchonas* of Weddell) are to be found, the leaves of which yield the alkaloids, *Cinchonine*, *Quinine*, *Quinidine*, and *Aricine* (?) called also *Cusco-chinchonia*. The presence or absence of these alkaloids, their relative amounts, and the facility or difficulty of separating them in a pure state, constitute the true criteria of the value of any bark—the old classification of pale, yellow, or red bark, being almost abandoned. "Dr. Weddell has proved that the young branches of several species constitute the *pale* barks of commerce, which become *yellow* or *red* in older plants, or in the older parts of the same plants." (Royle, 'Manual of Mat. Med.' 3rd ed., p. 482.) Besides, the manufacturer of quinine and cinchonine, uses those barks which yield him the largest returns, regardless of their appearance, names, or countries whence they come, when known. But the reckless destruction of many of the cinchona trees, diminishing the supply from the old forests, the selfishness of the monopoly company of La Paz, which aims at keeping up the price by limiting the supply, drives dealers to seek eagerly for barks which will meet the demand for the alkaloids. The barks presented for sale on their arrival in Europe, are generally recognised by the purchasers by the appearance, and to aid their judgments, the application of the methods of both qualitative and quantitative analysis, the fracture of the specimen, and the application of the microscope to transverse as well as longitudinal sections, afford considerable assistance. Even barks procured from the roots of the trees, a part formerly quite neglected, are now properly turned to account, such as that of the root or stump of *Cinchona calisaya*, var. *B. Josephiana*, Wedd.

The medical powers of a bark, as well as its price, is influenced by the circumstance of its being *coated*, that is, retaining the epidermis, or *uncoated*. The curative power of a bark is not dependent entirely on the quantity of its alkaloids, but on many of the other constituents. The activity of several barks has been estimated by Guibourt (Weddell's 'Hist. Nat. des Quinquina'), as follows; we give the commercial names:

1. Calisaya bark.
2. Orange-yellow.
3. Pitaya.
4. Red genuine, verrucous.
5. Red genuine, non-verrucous.
6. Red Lima (fine gray. *China Haanuco*).
7. Gray Lima.
8. Hurnalies, white verrucous.

The run on quinine as a therapeutic agent causes many barks to be undervalued at the present day, if they contain cinchonine only, or but little quinine, but Delondre justly anticipates a higher appreciation of these barks when the prevailing fashion shall change, or the high price of quinine drives chemists or physicians to use cinchonine, or quinidine. It is possible, that all the alkaloids (whether 3 or 4, for aricine is a doubtful one, and huanokina is merely cinchonine in a state of great purity), are only different combinations of a base, *quinogen*, with different proportions of oxygen. To avoid the expense of purification, hitherto very great in Britain, various preparations have been suggested, especially *amorphous quinine*; but the permission granted to chemists to use methylated spirit, somewhat removes the necessity for these expedients. There exists however in Paris a manufactory of an article intended expressly to adulterate sulphate of quinine.

The quinium of Labarraque, seems a very eligible preparation—also a wine of quinium.

Of comparatively recent preparations the *liquor quina ammoniatus* of Bullock, is the most quickly active—which renders it invaluable in influenza and other diseases attended with great debility.

In estimating the action of cinchona bark on the human system, it deserves to be borne in mind that the resin gives it a stimulating power, the kinate of cinchonine or quinine a tonic power, and the tannin an astringent property. By the first of these it approaches the balsamic stimulants and tonics, by the second the mineral tonics, while by the third it approximates to rhatany and catechu. Notwithstanding these resemblances, its action in the aggregate is strictly peculiar, so much so that all attempts to procure a substitute for it, whether among exotic or indigenous plants, have been attended with little success. It appears to act directly upon the nerves, particularly those of organic life, but its influence is speedily extended to the vascular and muscular system.

A moderate dose of cinchona taken into the stomach, and repeated in three or four hours, is followed by increased force and frequency of the pulse, greater firmness and constriction of the arterial tunics, augmented heat of surface, a flow of perspiration, and a universally improved tone of the system. The digestive and assimilating processes are greatly expedited, and the individual feels himself fit for exertions from which he would have shrunk before. This stimulating action does not cause vertigo or unpleasant derangement of the function

of the brain. The secretions of all the mucous membranes, however, are diminished, and in most persons the bowels become constipated, but occasionally an opposite state, or diarrhoea, is induced.

It is justly considered the most valuable tonic and febrifugal medicine we possess. The forms of administration are numerous. Powder is objectionable from its bulk, disagreeable taste, and difficult digestibility, owing to the quantity of woody fibre which it contains. Infusion is a good form, but does not possess all the virtues of the bark, which, however, are all taken up by the tincture: the spirit present in this last form is often an obstacle to its being given in a sufficient dose; it is therefore generally added to the infusion or decoction. Decoction, if the process be long continued, dissipates the volatile or aromatic portion, and diminishes its powers. The tincture is often formed by the addition of other substances, as in the compound tincture of bark, which is a valuable adjunct to other remedial means in weak subjects. Acids or ammonia are sometimes given along with it, according to the nature of the complaint.

The ease with which a small dose can be taken of the sulphates of quinine or cinchonine leads to the substitution of these preparations for that of the bark itself; and in many cases they are more eligible, but in others the want of the resinous and astringent principles renders these less proper. Perhaps the best and most convenient form, as it can be administered in a variety of ways, is one in which the bark is separated into its constituent parts, the woody fibre removed, and the other principles again united: this is called the aromatic kinate of kinia. It keeps well in all climates, is not bulky, and retains its efficacy for several years. For long voyages it is the best form into which bark can be put.

It is proper to direct attention to the great prophylactic power of cinchona, and its preparations, in warding off the fevers of tropical countries, especially in the exploring expeditions to the rivers of Africa. Very large doses of quinine administered to the crew, daily, of the vessels, as soon as they approach the miasmatic districts, has been found effectually to preserve them from the attack of ague and other fevers. It is requisite to continue to take the quinine, even after returning to Europe; for in some instances, where it has been taken continuously for six months after arrival in England, on its discontinuance, fever has manifested itself.

CINCHONETINE. [CINCHONA, ALKALOIDS OF.]

CINCHONICINE. [CINCHONA, ALKALOIDS OF.]

CINCHONIDINE. [CINCHONA, ALKALOIDS OF.]

CINCHONINE. [CINCHONA, ALKALOIDS OF.]

CINCHOVATINE. [CINCHONA, ALKALOIDS OF.]

CINNABAR. [MERCURY, Bisulphide of.]

CINNAMATES. [CINNAMYL, Cinnamic Acid.]

CINNAMEIN ($C_{30}H_{16}O_4$) is found in balsam of Peru. It contains cinnamic acid united to an ether.

CINNAMENE ($C_{10}H_8$) is formed when cinnamic acid is distilled with baryta.

CINNANIC ACID. [CINNAMYL.]

CINNAMIC GROUP. A group of organic compounds, belonging to the BENZOIC SERIES. The following are the names and formulæ of the chief members of this group:—

Hydride of cinnamyl	$C_{15}H_{17}O_2$
Anhydrous cinnamic acid	$C_{15}H_{11}O_2$
Hydrated cinnamic acid	$C_{15}H_{13}O_2$
Chloride of cinnamyl	$C_{15}H_{17}O_2$
Cinnamide	$N \left\{ \begin{array}{l} C_{15}H_{17}O_2 \\ H \end{array} \right.$
Cinnamene	$C_{10}H_8$
Styrone	$C_{10}H_8$
Cinnhydramide, or hydride of nitrocinnamyl	$C_{15}H_{17}N_2O_2$
Cinnanilide	$N \left\{ \begin{array}{l} C_{15}H_{17}O_2 \\ H \end{array} \right.$
Cinnitranside.	$N \left\{ \begin{array}{l} C_{15}H_{17}O_2 \\ C_{14}H_6(NO_4)O_2 \end{array} \right.$
Thiocinnole, or hydride of sulphocinnamyl	$C_{15}H_{17}S_2$

A description of some of these bodies will be found under their respective names. For that of the others the reader is referred to Gerhard's 'Traité de Chimie,' tome iii. 373.

CINNAMIDE. [CINNAMIC GROUP.]

CINNAMON and CASSIA. There are many contradictory statements about cinnamon and cassia. In the following account we chiefly follow Fr. Ludwig Nees von Esenbeck, who has paid great attention to the subject. According to him the finest or Ceylon cinnamon is procured from the three-year old branches of the *Cinnamomum Zeylanicum* (Blume), which is found native in the island of Ceylon only; the cultivation, however, has been extended to Java,

and to South America. Though found in various parts of the island, it is most abundant in the south-west part, near Colombo, and yields the best cinnamon when growing in a sandy quartz soil. The time for stripping off the bark is from May to October. The bark, after being removed from the branches, is tied up in bundles for twenty-four hours, during which time a sort of fermentation takes place, which greatly facilitates the separation of the outer part of the bark from the cuticle and epidermis, which is very carefully scraped off the Ceylon cinnamon. It is then rolled up into quills, or pipes, about three feet in length; the thinner or smaller quill being surrounded by larger ones; a mark which always distinguishes cinnamon from cassia. It is then conveyed to Colombo, where it is sorted by government inspectors into three kinds, of which the two finest alone were allowed to be exported to Europe, while the third, or inferior kind, was reserved to be distilled, along with the broken pieces of the other two, for the purpose of obtaining the oil of cinnamon. The select cinnamon is formed into bales of about 92½ lbs. weight, containing some pepper or coffee, and wrapped in double cloths made of hemp, and not, as stated by some writers, of the cocoa-tree.

This fine cinnamon occurs in pieces about forty inches in length, generally containing from six to eight rolls or quills in each, one within the other, of the thickness of vellum paper, of a dull golden yellow colour, smooth on both outer and inner surface. It is very fragrant, agreeably aromatic, taste pleasant, warm, aromatic, slightly astringent. Analysed by Vauquelin, it yielded volatile oil, tannin in large quantity, an azotised colouring matter, resin, a peculiar acid, mucilage, and feculum.

The root of the cinnamon-tree yields a kind of camphor, and the leaves yield an oil which resembles oil of cloves, which it is often used to adulterate. This is quite distinct from the oil of cinnamon obtained from the bark. The ripe berries yield by decoction a solid volatile oil, similar to the oil of junipers. Cassia, according to Marshall and others, is the bark of the old branches and trunk of the *Cinnamomum Zeylanicum* already mentioned, while others assert that is the bark of an entirely different species, namely, of the *Cinnamomum Cassia* (Nees Frates, et Blume), a native of China, but cultivated in Java. This last view is much the most probable: for not only is no cassia exported from Ceylon (except the rejected, or third sort of cinnamon, which is introduced into England incorrectly under that name), but almost all the cassia which reaches Europe comes from Canton, hence called on the Continent Chinese cinnamon. Reagents produce very different effects both on the infusion and oil of these two barks, which is a rational ground for believing them to be obtained from different species. Tincture of iodine renders decoction of cassia blue, but not cinnamon.

Cassia is easily distinguished from cinnamon. The bales in which it arrives are much smaller, containing only from two to four pounds, bound together by portions of the bark of a tree. The quills are thicker, rolled once or twice only, and never contain thinner pieces within; the diameter of the bark is much thicker than that of cinnamon, and harder, the outer rind less carefully removed (large patches of the cuticle and epidermis often remaining upon it), the colour deeper, of a brownish fawn colour (that raised in Guiana is yellowish), with the odour of cinnamon, but fainter, and less grateful, the taste more acridly aromatic, pungent, less sweet, at the same time more powerfully astringent, yet mucilaginous.

Cassia is often substituted for cinnamon, and it is also frequently adulterated with cassia lignea (which is the bark of a degenerate variety of the *Cinnamomum Zeylanicum* (Blume) growing in Malabar, Penang, and Silhet), with the bark of *Cinnamomum Culitlawan*, and with portions which by distillation have been deprived of their volatile oil. This yields the bitter cinnamon, but what is sold in the shops under the name of culitlawan bark, is, according to Blume, a mixture of several Indian barks, especially those of *Cinnamomum Sintoc javanicum* and *C. xanthoneurum*. The old "folia Malabathri" is a mixture of *C. nitidum* and other species.

Oil of cinnamon is obtained chiefly from the fragments which fall from the quills during the inspection and sorting at Colombo. These fragments are coarsely powdered, and after being immersed for forty-eight hours in sea-water, are distilled, when a milky fluid comes over, which separates into two parts, a light oil which floats, and a heavy one which sinks in the water. Eighty pounds weight of cinnamon yield about two ounces and a half of light oil, and five ounces and a half of heavy oil. About 100 gallons of oil of cinnamon are annually obtained at Colombo. As the oil which is met with in commerce is a mixture of these two, the specific gravity is variable, 1.035 to 1.090. In time a spontaneous separation takes place, and there are formed beautiful transparent crystals of a *stearopten* or cinnamon-camphor. Sometimes benzoic acid is formed. Oil of cassia is also obtained by distillation; at first it is whiter than oil of cinnamon, afterwards it becomes yellow, but never of such a fiery yellow as cinnamon-oil. The odour is agreeable, but not so delicate and cinnamon-like: taste, acrid, burning, but different from cinnamon. Specific gravity 1.0608: it reddens litmus paper. At a low temperature crystals show themselves, which disappear with an increase of heat. Some consider these a camphor, others benzoic acid. Benzoic acid unquestionably exists in this oil. Oil of cinnamon is adulterated with oil of cassia, with the oil of cassia-buds, with the oil of the *Cerasus lauro-cerasus*, or cherry-laurel, and it

is also said, with oil of bitter almonds, an exceedingly dangerous intermixture.

Cinnamon is an extremely valuable aromatic stimulant, and influences both the nervous and vascular system, especially of the stomach and intestines. It is of great utility in weakness of the digestive powers, unaccompanied with inflammatory action of the stomach; while in fluxes from atony of the intestines, its astringent properties, due to the tannin, render it a very useful medicine. It is the best of all condiments to be taken with food, particularly vegetables, during the prevalence or tendency to cholera. Even in fevers of an asthenic type, it has been advantageously joined with bark, and the compound cinnamon-powder is added to many medicines. Oil of cinnamon, given on sugar, is useful in cramps and other spasmodic diseases. Cassia has the same properties in less degree. Clove cinnamon, stated by some to be the produce of *Persea caryophyllacea* (Martius), is most probably the bark of the *Eugenia caryophyllata*, or of *Dicypellium caryophyllatum*, a native of Brazil. It has very little volatile oil.

CINNAMON, OIL OF. [CINNAMYL.]

CINNAMYL ($C_{15}H_{11}O_2$), the hypothetical radical essence of cinnamon.

Hydride of cinnamyl ($C_{15}H_{11}O_2 + H$) is the purified essence or oil of cinnamon. It is a fragrant oil, and forms with nitric acid a crystalline compound ($C_{15}H_{11}O_2 + NO_2, HO$), which, when mixed with water, is resolved into its original constituents, hydride of cinnamyl and nitric acid. When it is exposed to the air it absorbs oxygen, and becomes converted into *cinnamic acid* ($C_{15}H_{11}O_2 + HO$). This acid is also easily obtained by dissolving oil of balsam of Peru in a solution of potash in alcohol, evaporating to dryness, dissolving in hot water, and adding to the cinnamate of potash then formed hydrochloric acid. With bases it forms *cinnamates*. Nitric acid converts it into hydride of benzoyl. When added to cold nitric acid, it is converted into *nitro-cinnamic acid*. The salts of this acid detonate when heated. When cinnamic acid is treated with fuming sulphuric acid, *sulpho-cinnamic acid* is formed. [BALSAMS.]

CINNITRANISIDE. [CINNAMIC GROUP.]

CINQUE-CENTO STYLE. [RENAISSANCE.]

CINQUE PORTS. It has been a subject of controversy, whether this association of the maritime towns on that part of the English coast which approaches nearest to the Continent existed in any shape before the Norman conquest of England. Some writers have supposed that it originated with the Romans, and that the five stations of Regulbium or Reculver, Rutupia or Richborough, Dover, Lymne, and Anderida, probably the present Eastbourne, were selected by them as favourable points for protecting the southern coast, and no doubt as being also good ports. When the altered state of the shore rendered some of them no longer available as ports, the privileges, whatever they were, were transferred to other ports more favourably situated; and thus, as early as Edward the Confessor, only Dover continued, and the places of the other four were supplied by Sandwich, Hythe, Romney, and Hastings. Still of this there is no positive proof. The Domesday Survey only mentions three, Sandwich, Dover, and Romney; but Mr. Jeake, the town-clerk of Rye, collected the charters relating to the Cinque Ports, which were published in 1728, under the title of 'Magna et Antiqua Charta Quinque Portuum,' &c. In these the first charter of Edward I. confirms the peculiar privileges and liberties of the towns granted by his predecessors, of whom the first named is Edward the Confessor. From the Domesday Survey it appears that the three ports mentioned, on consideration of certain services to be performed by their shipping at sea, &c., were exonerated from such contributions and burdens as other towns were generally charged with; and these, it is reasonably thought, might have been enfranchised by the Confessor at one and the same time.

Though some part of the municipal constitutions of the individual ports may be anterior to the Norman invasion, yet the organisation of the general body, as it has existed in later times, is plainly traceable to the policy of the Conqueror, in securing, by every means, his communications with the Continent. These ports and their members occupy exactly the tract of sea-coast of which, after the victory of Hastings, he showed most eagerness to possess himself, by sweeping along it with his army before he directed his march towards London; and the surrender into his hands of the castle of Dover, which is the centre of the Cinque Ports' jurisdiction, was one of the stipulations introduced into the famous oath which, in Edward's lifetime, the duke had extorted from Harold. To enable his government to wield the resources of this maritime district with the greater vigour and promptitude, he severed it wholly from the civil and military administrations of the counties of Kent and Sussex, erecting it into a kind of palatine jurisdiction, under a *gardien*, or Warden, who had the seat of his administration at the castle of Dover, and exercised over the whole district the combined civil, military, and naval authority; uniting in his own hands all the various functions which, to use the terms most intelligible to modern readers, we may describe as those of a sheriff of a county at large, a *custos rotulorum*, a lord lieutenant, and an admiral of the coast.

To the five ports of the Conqueror's time were added, before the reign of Henry III., with equal privileges, what were called the *ancient*

towns of Winchelsea and Rye, lying on the Sussex coast, between Hastings and Romney. To each of these seven municipal towns, except Winchelsea, were attached one or more subordinate ports or towns, denominated *members* of the principal port. The following is a list of the Cinque Ports, and the two ancient towns, with their dependent members, as they stood at the commencement of the 19th century:—

PORTS.	DETACHED MEMBERS.
Hastings.	1. Corporate town of Pevensey; distant 12 miles from Hastings. 2. Corporate town of Seaford; distant 22 miles. 3. Part of Bexhill parish, in Pevensey Marsh; distant 8 miles. 4. Small part of St. Leonard's parish, near Winchelsea; distant 9 miles. 5. Beakshourne parish, near Canterbury; distant 48 miles. 6. Vill of Grange, or Grench, near Rochester; distant 50 miles.
Winchelsea.	
Rye.	1. Corporate town of Tenterden; distant 10 miles.
Romney.	1. Corporate town of Lydd; distant 3 miles. 2. Denge-marsh; distant 5 miles. 3. Orlestone; distant 10 miles.
Hythe.	
Dover.	1. Corporate town of Folkestone; distant 7 miles. 2. Corporate town of Faversham; distant 25 miles. 3. Parish of St. John, containing the town of Margate; distant 21 miles. 4. Parish of St. Peter; distant 19 miles. 5. Parish of Birchington; distant 20 miles. 6. Parish of Ringwould; distant 5 miles.
Sandwich.	1. Corporate town of Fordwich; distant 10 miles. 2. Corporate town of Deal; distant 6 miles. 3. Vill of Ramsgate, including the town of that name; distant 4 miles. 4. Vill of Sarr; distant 5 miles. 5. Parish of Walmer; distant 8 miles. 6. Parish of Brightlingsea in Essex; distant 40 miles.

It is probable that in very early times all the members were in some measure dependent on, or subject to, their respective ports; but in latter times there was no connexion between any port and such of its members as have been incorporated, beyond that which exists among all the ports, excepting only the connexion between Sandwich and Deal. Each incorporated member had within its liberty the same independent jurisdiction and municipal functions as the port itself. The unincorporated members remained under the municipal jurisdiction of their respective ports; they were within the jurisdiction of the criminal and civil courts, and of the magistrates and coroners of those ports; they were summoned on the juries, and contributed to the rates, in the nature of county rates, imposed by the justices of those ports. Yet none of the municipal franchises could be acquired in these members, nor had they any share in electing any of the officers of their respective ports; residence within them was not considered, for any corporate purpose, as residence within the port. The relation between Sandwich and Deal was peculiar. Deal was incorporated by William III., before which time it was exclusively under the jurisdiction of Sandwich. William's charter gave Deal a jurisdiction of its own; but as it did not interfere with the original jurisdiction of Sandwich, the latter retained a concurrent jurisdiction in Deal.

The internal constitution of each port, as well as the Norman denominations of *jurats* and *barons*, which, in lieu of aldermen and freemen, have constantly prevailed in them all since the time of William I., concur to show the solidity of his plan for rendering this maritime line one of the grand outworks of the Conquest. The earliest members of the municipal bodies established under these foreign denominations, at a time when the English municipalities in general were subjected to the most rigorous enslavement, were doubtless trading settlers from William's Continental dominions: and the term *barons*, as applied to the Cinque Ports' representatives, which in the later periods of English parliamentary history has usually been considered as simply synonymous with *burgesses*, did, before the several elements of the Commons' House coalesced into one homogeneous body, imply a political as well as a municipal superiority.

Until the time of Henry VII. the crown appears to have had no permanent navy: the Cinque Ports constantly furnished nearly all the shipping required for the purposes of the state, and their assistance to the king's ships continued long after that time. When ships were wanted, the king issued his summons to the Ports to provide their quota. In the time of Edward I. the number they were bound to provide was fifty-seven, fully equipped, at their own cost: the period of gratuitous service was limited to fifteen days. The summons in Edward III.'s time seems to have apportioned the ships among the ports and their members: some of the members had to provide one ship; and in some cases two members had to provide one between them. It is in consideration for these services that, in the preambles of the existing charters, the peculiar privileges and exemptions of the ports are stated to have been granted. These towns, owing to various causes, have long since lost their ancient importance. The physical changes that have taken place in the course of ages upon the coast-line may have had some effect. Rye and Romney, once standing on the

shore, are now at some distance from it. Sandwich is only accessible for small vessels; and Folkestone, one of the members of Dover, has only recently had its importance restored by becoming a station and port in connection with the South Eastern Railway. But the complete organisation of a permanent navy involved the extinction of that description of service on the part of these ports, in consideration of which their privileges were avowedly granted; and their inferiority as ports, and their distance from all the great seats of English manufactures, sufficiently account for their present commercial insignificance.

Each of the five original ports returned two *barons* to parliament, as early as the 18th of Edward I.; Seaford, a corporate member of Hastings, sent as early as the 26th of the same reign; and the two ancient towns, Rye and Winchelsea, sent as early as the 42nd of Edward III. The peculiar nature of the relation between the Cinque Ports and the crown must have given the latter, from the commencement, a very powerful influence in their internal transactions; and, in later times, when the parliamentary relations of the municipal towns came to be the grand object of solicitude to the royal prerogative, these municipalities imbibed an ample share of the prevalent municipal as well as political corruption. In the 20th of Charles II. the first open blow was struck by the crown at the liberties of the Ports in general, in the provision of Charles's charter of that year, by which the elections of all their recorders and common clerks were made subject to the royal approbation. Subsequently, in 1685, all the general charters of the Ports, and most of the particular charters of each individual town, were, by the king's special command, delivered up to Colonel Strode, then constable of Dover Castle, and were never afterwards recovered.

The lord-warden is the general returning officer for all the ports, the writs at every general election being directed to him in the same manner as to sheriffs of counties, whereupon he issues his precept for the election to the proper officer of each port. Before the Revolution of 1688 the lord-wardens assumed the power and the right of nominating one, and sometimes both, of the members for each of the port-towns having parliamentary representation; but this practice was terminated by an Act passed in the first year after the Revolution, entitled 'An Act to declare the Right and Freedom of Election of Members to serve in Parliament for the Cinque Ports.' The necessity for such an enactment proves how firmly the practice must have been established; but although this statute had the effect of taking away the privilege from the lord-warden, the result was, that the Treasury influence was enabled to return both members. The admittance of persons to the freedom of the ports became more and more restricted, till in most cases the right was almost solely vested in the corporations, and the corporations became family parties; corruption and bribery were established customs; and the freedom of a Cinque Port town was always considered as entitling its possessor to a provision of some sort. Repeated attempts were made, by trials in courts of law, and by election petitions to the House of Commons, to effect a reform in the representation; but though successful in one or two individual cases, there was no lasting improvement until the whole was effectively altered by the Reform Bill in 1832, and still further by the Municipal Reform Bill of 1835.

For all purposes except one or two, each corporate town of the ports possessed all the jurisdiction and arrangements of a separate county, and the circuit judges held no assizes within their liberties; each town, too, had its distinct rate in the nature and for the purposes of a county rate, and its civil court of record; and most of the duties analogous to those of a sheriff of a county at large were exercised separately and exclusively in each of the port towns. According to the originally uniform Norman constitution of the ports, the number of *jurats* in each corporation ought always to have been twelve, besides the presiding officer, each of whom was, *ex officio*, a judge both of the civil and criminal court. The mayor or bailiff, and two other *jurats*, constituted a quorum. It became, however, the practice in most of these towns to keep the number of *jurats* as low as possible, scarcely ever exceeding four or five. From the body of *jurats* in each port, or corporate member, the mayor or bailiff was elected, who frequently continued to hold the office for life or for a long period; and when the continuous holding was forbidden by the 9 Anne, cap. 20, the Act was evaded by two persons agreeing to hold the office in alternate years, or by appointing some mere dependent.

The jurisdiction of the Cinque Ports collectively extends along the coast, continuously, from Birchington, which is west of Margate, to Seaford in Sussex. But several of the corporate members are quite inland. Tenterden, in the centre of a rich agricultural district, has not even a river near it. Many of the unincorporated members are not only inland, but situated at great distances from their respective ports, some as far as forty to fifty miles. All the unincorporated members being exclusively under the jurisdiction of their own ports, each of those members was obliged to have recourse to the justices and coroner of its own port. Great inconvenience was experienced from this state of things, especially in those towns where the distance from the principal port was considerable.

The Parliamentary Reform Act of 1832 worked a considerable revolution in the political relations of the Cinque Ports. From three of the towns, Seaford, Winchelsea, and Romney, the right of returning members of parliament was wholly withdrawn; Rye and Hythe were

reduced to one each; and Hastings, Dover, and Sandwich, still return two each. In the several constituencies of these five remaining parliamentary boroughs, besides the important change effected by the introduction of the household franchise, the new regulation of the parliamentary boundaries made very material alterations. Hastings and Dover have experienced the least change in this latter respect. In the case of Hastings, the two nearest of the detached members have simply been added to the "home liberty" of the port itself, as before existing; and in that of Dover, the most populous part of one of the adjoining parishes has been added to the immediate liberty of the port. But in forming the new parliamentary borough of Rye, not only have the two "ancient towns" of Rye and Winchelsea been thrown together, but six surrounding agricultural parishes are also included within their common boundary. In like manner, Folkestone, a corporate member of Dover, is now joined with Hythe, and five adjacent agricultural parishes, in composing the parliamentary borough of Hythe; and to the ancient home liberty of Sandwich are added, for parliamentary purposes, the corporate town and parish of Deal, and the contiguous parish of Walmer.

The Municipal Reform Act has operated yet more decisively to break up the ancient organisation of the ports, and assimilate their internal arrangements to those of the improved English municipalities at large. The details will be found under the heads of the respective towns in the GEOGRAPHICAL DIVISION.

The jurisdiction in capital cases, formerly possessed by the ports, is abolished by the Act in common with all similar jurisdictions; and as regards the limits of the authority of the courts and magistrates of the ports, provision is made by section 134 of the same Act.

Anciently there were several courts, exercising a general jurisdiction over all the ports and members. The Court of Shepway was the supreme court of the Cinque Ports. The lord warden presided in it, assisted by the mayors and bailiffs and a certain number of jurors summoned from each corporate town. The following offences seem to have been cognisable within the ports' jurisdiction by this court only: treason, sedition, counterfeiting the king's coin or seal, and concealing treasure found. It was also a court of appeal from the judgments of the several local courts. This court has been so long obsolete that even the site of it is now unknown, except that it was most probably somewhere in that central part of the ports' jurisdiction about which lies the division of the county of Kent, still denominated "the lathe of Shepway." Two other ancient courts are still occasionally held, the Court of Brotherhood and the Court of Guestling. The name of the former seems to indicate its purpose to have been the regulating of the affairs of the fraternity or association of the ports in general. The latter court seems to have been only a modification of the former, practised on certain occasions. The Court of Brotherhood is composed of the mayors of the five ports and two ancient towns and a certain number of jurors from each of them. The Court of Guestling consists of the same persons, with the addition of the mayors and bailiffs of all the corporate members, and a certain number of jurors from each of them. It is thought that the bodies forming this addition may originally have been merely invited by the Court of Brotherhood to give their assistance, and that hence the assembly may have received the name of Guestling. The chairman of the court is called the speaker, and the office is filled in rotation by the mayors of the five ports and two towns, each for one year. The speaker sends a letter every year to each of the corporations composing the two several courts, asking their opinion as to the expediency of holding either of them; and if a majority answer in the affirmative, the speaker convenes the court. One of the more important functions of the Court of Brotherhood anciently was the appointment of the two bailiffs whom the Cinque Ports had the privilege of sending to superintend their affairs at Yarmouth in Norfolk, and the examination of the conduct of those officers. The securing of certain facilities for carrying on the fishery during the herring season, granted to them by charter, and enforced by successive royal ordinances, seems to have been the main object of the residence of these officers of the ports at Yarmouth, where also, together with the bailiff of that town, they had the keeping of the peace and the care of the prison during the fair, with the power of determining all disputes and complaints. As late as the reign of Elizabeth we find traces of the contentions which were constantly arising between the bailiff of Yarmouth and the bailiff of the Ports residing there. In the Court of Brotherhood, also, the arrangements and regulations were made as to the apportioning of the service of ships to the crown. In these general courts, too, assessments were made upon all the ports and members for defraying the general expenses of the association; and in them all disputes between any of the ports, towns, or members were settled, and complaints of misconduct in any of their officers were inquired into and redressed. The necessity for proceedings of this kind no longer exists; and although these courts have been occasionally held of late years, such holding seems to have been mere matter of form, excepting only the Courts of Brotherhood and Guestling held before each coronation, at which the arrangements have been made respecting the privilege of the barons of the ports to hold the canopy over the king's head on that occasion; another mark of the pre-eminence among the municipalities of England given to these towns by the princes of the Norman line.

It remains to notice more particularly the nature of the Lord

Warden's jurisdiction as now exercised. One important branch of a sheriff's jurisdiction is exercised by him over all the ports and members—namely, the execution of writs and the custody of debtors. All writs out of the superior courts are directed to the Constable of Dover Castle, who is always the lord warden, upon which his warrant is made out, directed to and executed by an officer called the *bodar*. This officer, by a curious anomaly, has also the execution of writs out of the distant civil court at Hastings; and the necessity of having recourse to him has been a source of inconvenience and dissatisfaction to the latter town. The clerk of Dover Castle acts as under-sheriff. The constable's jail for debtors is within Dover Castle; and by Act 54 Geo. III. c. 97, their maintenance is provided for by an annual contribution of 300*l.*, to be levied on the ports and members in proportions fixed by the Act. The lord warden has power to diminish this sum if he think it more than sufficient, and to increase it again. The money is paid over to the registrar of the Cinque Ports, who, at the time of the framing of the report of the late municipal commissioners, was the same person as the clerk of Dover Castle.

The admiralty jurisdiction of the Cinque Ports, attached to the office of lord warden, is expressly reserved in that clause of the Municipal Reform Act which abolishes chartered admiralty jurisdictions in general. A branch of this jurisdiction appears in the court of Lodemanage, so called from the old English word *lodeman*, a lead-man or steerer, which is held for the licensing and regulating of pilots, by the lord warden and a number of commissioners, of whom the mayors of Dover and Sandwich are officially two. The lord warden seems anciently to have held a court of chancery in one of the churches at Dover, but it has long been obsolete.

(Jeake's *Charters of the Cinque Ports*; Holloway's *History of Rye*.)

CIPHER is derived from the Arabic *Sifr*, which originally signifies "empty, devoid of," and is used as a substitute to denote the figure 0. The peculiar meaning of this symbol, and the important consequences of its use, gave to the Arabic arithmetic the name of *ciphering*, which it retains to this day.

CIRCE, one of the group of small planets revolving between Mars and Jupiter. [ASTEROIDS.]

CIRCENSIAN GAMES. [CIRCUS.]

CIRCINUS, the Compasses, a constellation of Lacaille, below Centaurus, and not very far from the South Pole. Its principal star is α , of the fourth magnitude, No. 1225, in the Catalogue of Lacaille, and 4835 in that of the British Association.

CIRCLE (*circulus*, a little circle, from *circus*, a ring), the figure formed by a point which revolves in a plane surface, and always preserves the same distance from a given point. The points of view under which this word might be considered are with reference, first, to its properties as a figure of geometry; second, to the history of the researches which were made for centuries, in order to discover the exact ratio of the circumference to the diameter; third, the effect of the properties of the circle upon several branches of mathematics. For the second, we refer to the word QUADRATURE; we shall give a few of the first, and a sketch of the third.

The word circle is sometimes used to denote the *circumference* or boundary line, sometimes the inclosed figure or area. Frequently a point *in* a circle means a point on the circumference; but a point *within* a circle always means a point in the interior. The *centre* is the point from which all the *radii* drawn to the curve are equal; a diameter is a double radius.

Draw a circle with a centre *O*, and let *OA* be any radius. Draw *AB* perpendicular to the radius, and *MN* also perpendicular to the radius. Take any points, *P* and *Q*, &c. Then among the most essential properties of the circle are the following:—

1. *AB* is a tangent to the circle.
2. *MN* is bisected (halved) by *V*.
3. The square on *VN* is equal to the rectangle (oblong), whose sides are *AV* and *VL*.
4. If any two chords (*MN* and *AQ*) cut in *W*, the rectangle, whose sides are *MW* and *WN*, is equal to that whose sides are *QW* and *WA*.
5. The square on *AB* is equal to the rectangle whose sides are *BG*

and BH , if the line BH be any line drawn through B , cutting the circle.

6. If Q move round the circle, and A and P remain fixed, the angle (opening) AQP preserves the same magnitude throughout, namely, half of the angle AOP , and equal to the angle BAP .

These properties, with several others which are *visibly* true, are in the third book of Euclid. We name one or two others, the verification of which will be a test of correctness in drawing for those who know how to use the compass and ruler.

7. From any point T exterior to a circle, two tangents TX and TY (of equal lengths) can be drawn. Let T be called the *pole* of XY . Then if any number of poles be taken on the same straight line (which call the polar line), all their chords pass through the same point; which last point is interior to the circle if the polar line be altogether exterior; and exterior, if the polar line cut the circle.

8. If any hexagon, having no opposite sides parallel, be drawn in a circle, the three points of intersection made by lengthening the opposite sides must be in one straight line.

To find the circumference of a circle (with more than sufficient nearness for practical purposes), take the 113th part of 355 times the diameter (AL) or 3.14159 times the diameter. To find the area in square units, multiply the number of units in OA by itself, and take the 113th part of 355 times the result (or multiply by 3.14159). Given the arc AP , and the radius OA , to determine the angle AOP . [ANGLE.] And the same for the inverse question. To find the area of the sector AOP in square units, take half the product of the units in the radius and the arc AP . These are the principal questions which can be solved by a person unacquainted with trigonometry.

The influence of the properties of the circle upon abstract mathematical analysis has been so great, that an attempt to describe the manner in which the means of expression derived from this figure have been used would fill a volume. We can only here give such a description as will help the beginner in trigonometry to extend his notions of the symbols he uses. Originally the sine, cosine, &c. [TRIGONOMETRY], meant certain lines drawn in a circle, with reference to a given angle at the centre. Each angle therefore had a sine, &c. for every different length which the radius might be conceived to have. But this introducing an unnecessary complexity into formulæ, it was thought sufficient always to suppose the radius a unit, which was however always expressed. Thus in the first stage of the science we have this theorem: "The sine of 30° is half the radius," which in course of time took this form, "The radius being 1, $\sin. 30^\circ$ is $\frac{1}{2}$." This method amounted to defining the sine, &c. to be, not the lines which they originally stood for, but the numerical ratios of these lines to the radius. Thus the sine, cosine, &c. became abstract numbers. The next step was to make the angle itself an abstract number, in the manner which [ANGLE] we have called the *theoretical* or *arcual* method of measurement; that is, instead of measuring the angle by an arbitrarily chosen angle, such as a degree or a minute, the numerical ratio of the arc to the radius became the measure of the angle. One extension more completed the subject. Angles of more than four right angles were admitted, conceived to be made by the revolution of a point, which was considered as having made more revolutions than one. Thus any number represented some angle, and had its sine, cosine, &c. And the angles themselves being abstract numbers, and also their sines, &c., it followed that all the propositions of what was trigonometry, an application of geometry, became the propositions of trigonometry, a part of pure arithmetic; retaining indeed the old names derived from geometry (names are never changed, witness the use of the term *square* in algebra), but based upon the notion of number, and the symbolic operations of algebra. Thus though it will always perhaps be thought desirable to lead the beginner through the gate of geometry, yet there must come a time, if he continue his studies to the higher branches, when he will consider a sine as a number, a function of a number; for instance, x being a number, the sine of the number x means the series

$$x - \frac{x^3}{2.3} + \frac{x^5}{2.3.4.5} - \&c. \text{ ad inf.},$$

or any algebraical form which is equivalent to it.

This is the point to which works on trigonometry are rapidly tending; and seeing that the student must end, if he pursue his course, in such considerations, it is most desirable that he should begin in the same manner, to every extent which is consistent with not forcing abstractions upon him too rapidly.

The ratio of the diameter to the circumference of a circle is very near indeed to that of 113 to 355, which numbers this diagram will keep in memory.

$$1 \quad 1 \quad 3 \quad | \quad 3 \quad 5 \quad 5$$

This method makes the circumference too great by about twenty-seven hundred-millionths of the diameter, and is therefore abundantly exact. But for common purposes, take the circumference at three times the diameter and one-seventh of the diameter, which does not err more than about one part out of a thousand of the diameter, and still in excess; that is, the circumference is a little less than twenty-two-sevenths of the diameter.

CIRCLE, ASTRONOMICAL. Though almost all the astronomical

and geodesical instruments which are at present used in measuring angles, are composed of entire circles, the term *astronomical circle* is ordinarily confined to those instruments of which the sole or principal use is the measurement of angles of altitude or zenith distance. In the present article we shall adopt this limitation, and restrict ourselves still further to a description of the construction and use of those circles which are either fixed in the plane of the meridian, as the *mural* and *transit* circles, or which continue to have the plane of the principal circle vertical, though turning upon an axis, as the *altitude* and *azimuth* circle. For other instruments which might be included under the term circular, the reader must consult the articles EQUATORIAL, REPEATING CIRCLE, and THEODOLET.

Fig. 1.

This article will be more intelligible with some preliminary explanations.

Let a circular plate, divided into 360° , turn round a concentric axis C , fixed into the block $S\ N$, so that the line EO , moving with the circle, and in which direction the observer is supposed to look, can be placed in any direction up or down: A and B are two pointers attached to the block, and in a line passing through the centre. The block and circle are supposed to be upright; the axis C and the line AB horizontal. Also, when the line of sight is vertical, or EO coincides with $z'z$, 0° of the divisions ought to be exactly under the pointer A . It is evident, when the line of sight is moved through any angle into the direction EO , that $C\ 0^\circ$ must have moved through an equal angle, and that the $\angle ZCO = \angle ACO$, or the arc AO . Hence, if an object is seen in the direction EO , its *zenith distance* ZCO will be the angle pointed out upon the divided circle by the pointer A . This angle is technically called the *reading* of A . The line EO represents the direction of plain sights, or the line of sight of a telescope, sometimes called the *line of collimation* (from *collimare*, said by Facciolati to be a mistake for *collineare*).

If, when EO is vertical, A points a little above or below the 0° , or zero of the divisions, the difference from 0° is called the *error of collimation*, which may be corrected by shifting the position of A ; but when the quantity and direction of the error are known, there is no need to make any alteration. For instance, let A point to 2° when the line of sight is vertical, then it is evident that when the line of sight is in the direction EO , the zenith distance will be equal to the arc from 2° to A , or 2° must be *subtracted* from the *reading* of A . If EO be directed anywhere between Z and N , then 2° must be *added* to the readings of A . In fact, the pointer may be placed anywhere in the circumference of the circle, and the divisions may commence in any part of the circle without at all affecting the accuracy of the measurement of angles of zenith distance; but a very large error of collimation would be inconvenient in practice. The second pointer B , if exactly in a diameter with A , and the divisions perfect, would evidently give the same result as A . This also may have an error of collimation, which may be treated precisely as that of A ; or rather, the error of collimation for the *mean* of two or more pointers is determined at once and by the same operation. Two readings have this advantage over one, that if some of the divisions should be erroneously placed, it is not likely that equal errors in the same direction should fall at the same time under both pointers; and in any other supposition, the mean of the two readings will be affected by a less error than one of them. Hence the advantage of multiplying the readings for lessening the errors of division; it is evident that what is improbable for two, will be all but impossible for six, which is the number used in the Greenwich circles. There is.

however, another and more sensible advantage in two opposite readings above one. Conceive the whole circle to be moved towards z , or z' , or pushed sideways towards n or s ; still, so long as EO continues to be parallel to itself, which it must be if it continues to be in the direction of a very distant object, the sum of the readings of A and B will remain the same; whatever one loses the other will gain. Hence it is not necessary that the axis should be truly circular, or that the centre of the axis should be exactly concentric with the centre of the divisions, which last requisite is not easily accomplished in the present construction of English dividing engines. In all circles which have readings diametrically opposite to each other, the observer ought to consider each pair as only one reading of a diameter, and not as two unconnected readings. There is another form in which a circular instrument for measuring altitudes may be constructed; the divided circle may be fixed to the block, and the line of sight, EO , turn upon the axis c . In this case the pointers must be connected with EO , and revolve on the same centre. All the previous remarks are equally applicable.

The operation of noting the angles, or of *reading off*, has been described in its rudest form, as it seems to have been practised by the Greeks. We must here explain somewhat more minutely the use of the micrometer microscope. (For other modes of subdivision, see *VERNIER*.)

Fig. 3.

Fig. 2 is a *micrometer microscope*: AB is supposed to be the space between two divisions of the circle which is generally equal to $5'$. The object glass G , which is sometimes, and with great benefit, made achromatic, forms at ab an inverted image of AB , as $a'b'$. Within the body of the microscope there is a slide, represented in fig. 3. This slide is drawn forwards by a fine screw (generally of 100 threads to an inch), while it is held back by a spring to avoid *lost time*; it has two fine wires crossing at an acute angle, as in the figure. The image AB should fall exactly on this cross, and the two lens eye-piece should be so placed as to give distinct vision of both. Also five revolutions of the screw should move the cross *exactly* from any division of the circle to the neighbouring one. The circular plate H is fixed by friction upon the head, and is divided into 60 parts, which correspond to seconds on the circle, and are read off by a pointer, I . The entire revolutions of the screw are counted by a sort of comb, or indented plate fixed near the wires, but not moveable with them. There is a little projecting tongue of metal opposite the cross wires, which is seen between the teeth of the comb at each whole revolution of the screw. This microscope having its parts at the proper distance from each other, and being placed at the proper distance from the divided circle, must be supposed to be substituted for the pointer A in fig. 1 (p. 924); the tongue at O in the comb, and the zero of the divided head opposite to its index. If a division of the circle seems exactly to cut the cross at the angular points, the observer has only to note what division of the circle it is, and that is the reading, just as with the simple pointer. Generally, however, one division will appear above and another below the cross. Since the divisions are seen inverted, the division apparently below the cross is the one really above, which, according to fig. 1, and the position EO , is the division immediately less than the position of the microscope or pointer. Turn the screw round until the appearance is exactly the same as in fig. 4, and suppose that the tongue has moved over two teeth, showing two revolutions of the screw, and the index is half way between 33 and 34 on the divided head, then $2'$ and $33.5''$ are to be added to the degrees and minutes of that division. Now that division

is $50^\circ 5'$; therefore the true reading is $50^\circ 7' 33.5''$. What has been said as to error of collimation holds good with a microscope as with a pointer. When the line of sight EO falls between z and n , then the next least division will be really below, but apparently above the cross, and the measurement should be made to it. The screw in this case must be turned the other way, and instead of the divisions of the head shown by the index, their difference from 60 must be taken for the seconds. A little caution and experience will guard the observer against mistake. The length of the microscope can be altered by screwing the tube in which G is fixed, and the microscope can be shifted in its support to and from the circle by the nuts kk , $k'k'$. It is evident that by these two movements the size of the image can be altered as well as its situation with respect to the cross wires. (See the figure of the altitude and azimuth circle for the mode of mounting the micrometer.) The apparatus of the micrometer microscope, shown at fig. 3, is frequently attached to the eye-end of a telescope, and is placed in the focus of the object glass. The wires are then placed across the slide and at right angles to it, so as to be parallel with other wires of the telescope. If these points are clearly understood, the reader will find no difficulty in understanding the rest of this article. [*MICROMETER*.]

The earliest application of a circle to astronomical purposes is described by Ptolemy ('*Almag.*' i. 10), who calls it, from its use, a *solstitial circle*. This consists of a smaller circle turning freely within, and in the same plane with, a larger and fixed divided vertical circle. Two small projecting prisms are placed in a diameter of the inner circle for a line of sight, and pointers are also fixed on the inner circle, which move on the face of the outer circle. The instrument thus formed is to be carefully adjusted by a plumb-line and meridian-line in the plane of the meridian. In observing the sun, the inner moveable circle was turned round until the shadow of the upper prism exactly covered the lower prism, when the pointers marked the corresponding division upon the outer fixed circle. The inner circle seems to have been employed as the most accurate mode of giving a rotatory motion to the *line of collimation*, concentric with the divided circle. If a bar, carrying the line of sight and the pointers, be supposed to revolve on an axis, it is the second case of fig. 1. The language of Ptolemy does not inform us who was the inventor of this instrument, or even that it was ever made or used. Delambre conjectures, with some probability, that it is due to Eratosthenes, though he inclines to think that the celebrated measure of the obliquity of the ecliptic by that astronomer—namely, that the distance between the tropics is equal to $\frac{1}{13}$ of the circumference—was deduced from observations with the gnomon. However that may be, it is certain that the *solstitial circle* was the best-contrived instrument of which we find any account until the time of Roëmer; and it bears, as will be seen, a very close analogy to the modern mural circle of Troughton.

Except the complicated astrolabe of Hipparchus, which consisted of five concentric circles, so contrived as to have one circle in the plane of the ecliptic, and another at right angles to it, we do not find the entire circle employed in large instruments before the time of Tycho Brahe, and then only for an equatorial. The supposed authority and example of Ptolemy, who proposed a quadrant, and the desire of increasing the sensibility of instruments, by enlarging the scale of the divisions, blinded astronomers to the more solid advantages of the entire circle.

In 1704 Roëmer erected his *Rota meridiana*, or *transit circle*, in his private observatory 1^m due west of the astronomical tower of Copenhagen. He had invented the simple transit and the altitude and azimuth circle about fourteen years earlier, and in this new instrument he very happily combined the qualities of a transit telescope with those of a meridian altitude circle. In a letter to Leibnitz, 15th December, 1700, he had already said, "that the quadrant and sextant ought no longer to be used, and that he would rely more on an entire circle of four feet than on a quadrant of a ten-feet circle." ('*Miscell. Berolin. continuat.*' ii. p. 276.) A description and figure of the *Rota meridiana* are to be found in the '*Basis Astronomiæ*,' p. 143, tab. viii., of his pupil Horrebow, '*Hafniæ*,' 1735, with a specimen of three days' observations. The altitude and azimuth circle is described in p. 43, and figured in tab. ii. of the same work.

The *Rota meridiana* of Roëmer was a divided circle set upon a hollow double cone, at right angles to the axis of the cones, and concentric with them, the circle being near one end of the axis. The divisions were read by two microscope verniers, fixed in a diameter of the circle on one of the supports of the axis. For general purposes, this is perhaps as well a designed instrument as has ever been constructed, yet it was not imitated till a similar construction was recommended by Mr. Pond, and adopted for the observatory at Paramatta. A second, on a much larger scale, was somewhat later made for the observatory at Oxford; both these were by Mr. T. Jones. Notwithstanding the advice and practice of Roëmer, it does not appear that the entire circle was used for astronomical purposes until Mayer proposed his *repeating reflecting circle*. His description was published in 1770 ('*Tabulæ Solares*,' p. 21, plate ii.), but the repeating reflecting circle did not come into use until modified and perfected by Borda about 1787.

In 1784 the Danish astronomer Bugge published his '*Observationes Astronomiæ, Hauniæ*,' in which he gives a figure and description of a vertical circle of four feet diameter revolving in azimuth, p. liii.

Tab. viii. and ix.; it seems a smaller one had been used in the survey of Denmark as early as 1762.

Ramsden undertook an altitude and azimuth circle for the observatory of Palermo in 1788, and completed it in 1789. This is described by Piazza (*'Della Specola Astronomica di Palermo,'* 1792), with four plates of the instrument and its details. (See, also, Pearson's *'Astronomy,'* vol. ii., p. 413, plate xxiii.) It is with this circle that the declinations of Piazza's celebrated catalogue were determined. In 1792 Troughton perfected his altitude and azimuth circle; and in 1793 Mr. Francis Wollaston published in the *'Philosophical Transactions'* a description, with a plate, of his transit circle: Borda's repeating circle seems to have been first used about 1787, in connecting the meridians of Paris and Greenwich. The advantages of the circular form were now appreciated; its superior strength and symmetry, the elimination of any error of excentricity by opposite readings, and

the diminution of errors of division by increasing the number of readings, or by reversing the instrument, were placed beyond dispute. Various alterations were made in parts of these instruments, and new contrivances and conveniences applied, but nothing very novel in principle was struck out till Troughton erected a six-feet mural circle at Greenwich in 1812. After some controversy this form has been generally adopted in those British observatories which can afford a second observer for the transit.

The limits of the present work will not allow a detailed account of any one instrument, and still less a description of the numerous variations which have been introduced according to the views of astronomers and artists. We shall give a general view of the two most essential forms, the mural meridian circle and the altitude and azimuth circle, as constructed by Troughton and his school.

The accompanying figure of the mural circle of Troughton is copied

Greenwich Mural Circle, by Troughton; diameter six feet.

from that prefixed to the Greenwich Observations for 1812, with the subsequent alterations. The circle is framed as strongly as possible (it might perhaps, in some cases, be advantageously cast in one piece), and is fixed at right angles to, and concentric with, a long, hollow, conical axis. This axis rests and turns in two collars, one towards each end of the cone, fixed at the front and back of a stone pier, three or four feet in depth, and there are four screws at the back for adjusting the horizontal axis in inclination or azimuth. The circle is divided on its edge to 5', upon a narrow ring of gold or other metal let into the rim; the divisions are read by six micrometer-microscopes at A, B, C, D, E, F. The telescope is fixed at right angles upon an axis which works within the hollow conical axis of the circle, and can be moved upon the circle into any position; it is held fast by clamps towards the object and eye-end. At the eye-end there are three or more vertical, and one horizontal wire, and a micrometer, which carries a second horizontal wire parallel to the fixed wire. To prevent wear, and to give ease and smoothness to the motion of the circle, two large friction wheels are suspended in front of the pier from the arms of two levers, which by counterpoises may be made to support the whole or part of the weight of the instrument. They press upwards upon a ring on the axis, between the circle itself and the pier. There are

several small contrivances which need not here be mentioned, as our design is only to give an idea of the nature of the instrument. For a more minute description the reader must consult Pearson's *'Astronomy,'* vol. ii. pp. 472, 488, plate xx. The above description belongs to the mural circle as constructed by Troughton. In one or two later instances the collars have been exchanged for Y's, that is, angular notches in pieces of metal, in the hope of making the instrument serve for a transit; but this has not, we believe, yet been performed satisfactorily. Dr. Robinson in the circle made for the observatory at Armagh, preferred having the divisions cut on the back of the instrument, and the microscopes fixed on the edge of a circular pier, with several other alterations (for which see *'Mem. Ast. Soc.,'* vol. ix.) The divisions of the circle are cut by Troughton's method. [GRADUATION.]

After the instrument is erected on its pier, the axis must be placed horizontally, or the plane of the circle vertical. This may be done by a plumb-line apparatus, which generally accompanies the instrument; or more accurately by making a star pass the meridian wire at the same time when seen directly, and also when seen reflected in a trough filled with mercury or water, &c. The four screws at the back of the pier supply the means of effecting this. The second adjustment, or

placing the line of sight at right angles to the axis, may be performed by two distant marks to the north or south of the circle, which have been previously correctly placed by means of a transit; or by a collimating transit [COLLIMATOR]; and finally, the instrument may be placed in the meridian, either by a mark, or by observations of circumpolar stars above and below pole, or by observations of high and low stars, just as a transit. [TRANSIT.] Or the position of the plane described by the line of sight with respect to the meridian, may be determined by comparing the passages of stars over the meridian, as observed with the circle and with the transit at the same time: when the law of the errors being known, and also the amount of their sum, their respective values are easily ascertained and corrected. It may, however, be remarked, that small errors in any or all these adjustments will not vitiate the results; and that the moon is the only celestial body sensibly affected by ordinary variations from the true meridian.

The mural circle is used in measuring angular distances on the meridian, and the observation is performed thus: The telescope is pointed nearly in the direction of the object, and the circle fixed by the clamp in that position: then the instrument is moved by the slow motion-screw of the clamp, until the horizontal wire exactly cuts the star in two, or *bisects* it, at or near the meridian wire. If the object be the sun or moon, or a planet having a considerable disc, the wire is made a tangent to its illuminated edge. With the sun, a dark glass is put on the eye-end to protect the sight, and at night a lamp placed opposite the centre of the telescope throws light through a glazed aperture, which is again reflected by a polished metal ring placed at an angle of 45° with the axis of the telescope, so as to illuminate the field of view and show the wire distinctly. This light can be modified at the pleasure of the observer, and the apparatus for this purpose is shown on the telescope. The mural circle has been used somewhat differently by different observers. When Troughton proposed a mural circle for Greenwich, he said that all observations should be considered as distances from the pole; and that the place of the pole on the instrument (that is, the reading of the circle when the telescope points to the pole) should be determined from the successive upper and lower culminations of Polaris, and other close circumpolar stars. The north polar distances of stars might thus be measured and registered with the help of a correct table of refraction, without an accurate knowledge of the latitude of the place, which is only wanted for converting polar distances into altitudes or zenith distances, for computing refraction and parallax. The latitude of the observatory might be subsequently deduced by comparing the polar distances of stars near the zenith, for instance, of γ Draconis at Greenwich, with the zenith distance of the same star observed by the zenith sector or the zenith tube. [ZENITH SECTOR.] The observations could be checked by combining them with observations by reflection, when the star is seen reflected from the surface of a trough of quicksilver. In a climate so variable as that of England, Mr. Pond, then astronomer royal, found it advisable to modify the plan thus suggested. He first formed an approximate catalogue of the north polar distances of several stars by these or other means, which he perfected as follows: Assuming the approximate catalogue to be correct, every future observed place, compared with the place computed from the catalogue, presented a difference, which he called the *index error* of the instrument, and from the observations of several stars he obtained a *mean index error*. This mean index error was then applied to each of the observations, and a corrected catalogue thus produced, which by repeating the process leaves no constant error except such as may be common to all the stars employed; such, for instance, as an original error in assuming all the polar distances too large or too small. Now an error of this nature affects all the stars at their superior passage alike, and makes them all equally appear too near to or too far from the pole; but it affects the superior and inferior passages of the circumpolar stars by equal and contrary quantities. Hence the difference between the mean of two sets of observations of Polaris and other circumpolar stars, one set being deduced solely from upper, and the other solely from lower culminations, is clearly equal to twice the mean error in the assumed place of the pole with respect to the stars; and this correction being applied to all the stars, a new and more correct standard catalogue was formed, to be again corrected and improved by future observations. It is evident that the errors of the originally assumed catalogue are now wholly eliminated. By shifting the place of the telescope on the instrument, fresh divisions were brought into use for each star. The accuracy of the tables of refraction employed might have been tested by the agreement of near and distant circumpolar stars, in assigning the same value for this correction to the polar point. The only defect in this method seems to be, that it assumes the accuracy of the instrument or the accuracy of the tables of refraction; and that if either or both be imperfect, the final results are not in a form suited to investigation.

Another mode was adopted by Mr. Pond after 1824, when a second mural circle, made by Mr. T. Jones, of Charing Cross, was erected at Greenwich. Suppose several stars to be observed the same evening in two groups, which call A and B. All the stars in group A are observed by both circles by direct vision; the stars of group B are observed directly by one circle, suppose Jones, and by reflection, by Troughton. Let the mean of the readings of group A, by Jones, exceed the mean of the readings of the same group by Troughton, by m'' ; then it is

clear, the instruments continuing in the same state, that if from the observation of any other star, by Jones, you *subtract* m'' , you will have the reading which Troughton would have shown, barring accidental errors, and *vice versa*, that on *adding* m'' to any observation by Troughton, you will get the corresponding observation, with the same exceptions, which would have been made by Jones. Again, let a star in group B be taken, and let D be the angle read off by Jones, the star being then seen directly, and R the angle by Troughton, the star being seen by reflection. Then, according to what has been said above, $D - m''$ is the angle which Troughton would have given by direct vision, and consequently the angle between the star seen directly and by reflection, which is twice the altitude of the star, $= R - D + m''$,

or the altitude $= \frac{R - D}{2} + \frac{m''}{2}$. Again, as the reading which corresponds

to the horizontal position of the telescope is evidently $D + \text{altitude of the star by Jones}$, and $R - \text{altitude or depression of the star by Troughton}$, we shall find for that reading, or the *horizontal point*, as it

is called, in Jones, $\frac{R + D}{2} + \frac{m''}{2}$, and in Troughton, $\frac{R + D}{2} - \frac{m''}{2}$. In

this way each of the stars in group B gives a fresh value for the horizontal point in each instrument, and the *mean* of the determinations for each circle is taken as the basis for reducing every observation by that circle. Thus the reading of each direct observation of the stars in group A with Troughton, being *subtracted* from the mean value of its horizontal point, will give the true altitude of the stars in group A, and the same value of the horizontal point being *subtracted* from every reflected observation of group B, by this circle, leaves in like manner the true altitude, which is all the astronomer demands from the circle. This method requires the groups A and B to be sufficiently numerous for eliminating the chance errors of mere observation, and to be distributed over various parts of the circle to destroy faults of form or of division. It is also supposed that the circles are instruments of nearly equal goodness, and that each is as perfect as art can make it. If they should be defective, the discrepancies in the partial determinations of the horizontal point will show it, and the astronomer must then attempt to discover the law and the cause of the defect. The combination of two circles to form, as it were, one instrument, has only been tried at Greenwich, but there it has proved eminently successful; Mr. Pond's opinion, after long experience, being, that *the pair were more than twice as powerful as a single one*. The same astronomer suggested an analogous method for one circle. Observe the groups A and B all *directly* one night, and on a following night observe A *directly*, and B by reflection. A comparison between the groups A on different nights (the change of place in the stars and in the refraction being allowed for) will give you the variation or change of place of the instrument and microscopes; and by applying this to the stars B, observed on either of the nights, you will have observations of the same stars on different nights, by direct and reflected vision, but with an *unchanged* instrument. Hence the double altitudes of B are found, and also the horizontal point for one of the nights which when increased or diminished by the variation above found, is the horizontal point for the other. This method, or one similar to it, is, we believe, followed at Edinburgh and the Cape of Good Hope; and it is found that these instruments are so steady and unfluctuating, that the same value of the horizontal point results from the observations of several days. In this system the observations of one day are made dependent on those of another, when the atmospheric circumstances may be widely different. It has, however, one advantage over the previous method with two circles, that it places more directly in evidence the individual errors of the instrument. The differences which may be found between the partial determinations of the horizontal point on the same night, and on different sides of the zenith, will show what reliance is to be placed on it and on the observer.

When the mural circle was erected at Cambridge, Professor Airy selected the following plan of determining the horizontal or zenith point. The micrometer attached to the eye end of the telescope has already been mentioned. The value of a revolution of this micrometer having been very exactly measured, and the parallelism of its moveable wire with the horizontal wire carefully ascertained, and also the reading of the divided head when the two wires coincide, the telescope is set pretty nearly in the position at which a star by *reflection* would be on the horizontal wire, the circle is then firmly clamped, and the microscopes are read off. When the star is at a convenient distance from the meridian wire, it is bisected by the micrometer wire without stirring the circle. When this is done, and the time noted, the circle is unclamped, and the star bisected by *direct vision* on the fixed horizontal wire, by turning the whole circle round, and the time is again noted. If the star had been observed in both instances upon the meridian and upon the fixed wire, it is clear that the reading corresponding to the horizontal position of the telescope would be half way between the readings of elevation and depression, or $= \frac{R + D}{2}$. The cor-

rection to the meridian is easily found and applied, the times being known. Again, if the distance between the fixed and micrometer wire be equal to n'' , it is clear that the reading of R is greater or less by n'' than it would have been if the observation had been made with the

fixed wire, and that the further correction for the micrometer is made simply by the addition or subtraction of $\frac{n''}{2}$ to the value already found

of the horizontal point. In the Cambridge Observatory, Professor Airy tabulated the reading corresponding to the zenith position of the telescope. From a mean of such determinations the reading of the

zenith point is settled, and all observations made in the ordinary way, reduced to altitudes or zenith distances. For this mode of observing, the micrometer should be exquisitely perfect, and carefully watched. On comparing the zenith points deduced from low and high stars, to the north and south of the zenith, Professor Airy discovered some anomalies, the causes of which have not yet been fully ascertained. ('Cambridge Observations,' 1833, p. 27.) They seem, however, to

Eighteen-inch Altitude and Azimuth Circle, by Troughton and Simms, 1836.

exist in other mural circles, and possibly in circles of a different construction.

The micrometer microscopes, in what has been said, are supposed to be exactly adjusted, so that five revolutions of the screw carry the cross of the wires precisely over a space of 5' on the circle. It is not possible to make this adjustment with perfect accuracy, nor would it be permanent; but it is not necessary. By examining the value of the *runs*, as they are called,—that is, the measures in revolutions and parts of the

screw of the 5' spaces in the circle,—a mean value of the measures of 5' by the six microscopes is obtained, from time to time, which may be a little greater or less than five revolutions. In this case, the mean of the micrometer readings—that is, of the single minutes and parts—must in each observation be altered in the proportion of the value thus ascertained to be 5'. If, for instance, the mean value of the 5' spaces on the circle were apparently 5' 5.1" by the microscopes, $\frac{1}{10}$ must be subtracted from the minutes and seconds indicated by the mean of the

microscopes. For actual adjustment, the following directions may be useful: A micrometer microscope is adjusted when the image of the divisions of the circle is formed upon the cross wires of the microscopes, and its size is exactly equal to five revolutions of the screw. Suppose the vision of the wires and of the divisions to be perfect, but that the space of 5' is passed over by four revolutions and fifty parts of the screw. It is evident that the image is too small, and it must be made larger by drawing out by the screw the object glass *a*, and bringing it nearer the limb. In this case, however, the image is formed between the wires and the eye-piece, and therefore the whole body of the microscope must be drawn from the circle until the image falls on the cross wires. It will now be found that the image of 5' is larger than before, and it must be again measured by the screw. In this way, by gradual attempts, the microscope may be perfectly adjusted, but the operation, if complete accuracy be aimed at, is very fatiguing and troublesome.

The general form of the altitude and azimuth circle will be seen from the woodcut. The lower, horizontal, or azimuth circle, is fixed on three strong radii, which have foot-screws at their extremities, and a strong vertical steel axis rising from their intersection. On this axis the whole of the upper works move freely and smoothly on a conical cap accurately fitted and ground to the top and bottom of the axis. On the lower part of the cap is fixed a broad circular plate on which the two pillars rest which support the circle and telescope. The microscopes for reading the azimuth circle are fixed on the pillars. Outriggers stand on the top of pillars, each of which carries a notch or Y, which can be raised or depressed by a screw. The vertical, altitude, or declination circle is framed with a view to strength and lightness, and its divided face is read by two microscopes placed on the end of the curved tube, which is formed something like a pair of horns, and fixed across the top of one of the pillars. The circles are usually divided to 5', and subdivided by the micrometer microscopes to seconds. The graduation of the horizontal circle generally runs from 0° to 360°; the vertical circle is differently divided, according to the pleasure of the artist or observer. A little consideration will enable any one to apply the rules given for reading microscopes to each particular case. We shall speak indifferently of altitude and zenith distances, since they are immediately derivable one from the other. The wires of the telescope are illuminated by a lamp which shines in at one end of the cross or transit axis of the vertical circle, and is reflected on the wires by a pierced polished ring set diagonally. There are two sensible ground levels, one of which is attached to the horns supporting the upper microscopes; another, which is free, can be applied through the openings of the circle to the pivots of the cross axis. The cross level and its adjusting screws will be understood by the accompanying figure.

There are clamps and slow-moving screws to each circle to fix them, and to give the power of bisecting any object with the telescope.

Detached or Transit Level.

The first adjustment is that of setting the vertical axis perpendicular to the horizon. Turn the instrument until the fixed level is nearly parallel to two of the foot-screws, and place the bubble in the middle by the foot-screws. Then, moving the instrument half round in azimuth, bring the bubble again to the middle, half by the foot-screws, and the other half by the screws which raise or depress one end of the level. If this is carefully done, and the circle restored to its original position, the bubble will be still in the middle; but if not, it must be brought there, half by the foot-screws, and the rest by the level-screw. Now, turning the instrument a quarter round, through 90°, bring the bubble into the middle of the scale by touching the third foot-screw. This is generally placed in front and towards the observer, and rests on a small lever apparatus, represented in the figure, which supplies a very delicate slow motion, contrived, we believe, by Borda. When the operation is successfully performed, the bubble will remain in the centre, whatever azimuth the instrument is directed to. It is not necessary in practice to touch the screw which adjusts the level if the error be very small. The divisions of the level-scale corresponding to

both ends of the bubble should be noted before and after reversion, and the mean taken. Let the foot-screws be called *E* and *W*, and the ends of the level towards them be distinguished by the same letters, and the scale of the level be numbered from the centre to each end, and suppose the readings be—

	<i>E.</i>	<i>W.</i>
In the first position	67.4"	48.2"
In the reversed position	59.6"	56.0"
Mean	63.5	52.1

difference = 11.4".

The mean readings would have been the readings of the level, if the level itself had been in adjustment. It is evident that *E* is too high, or *W* too low, by half the difference, or by 5.7", and one of the foot-screws must be turned enough to shift the bubble 5.7" in the right direction. Troughton always moved both *E* and *W* an equal quantity in contrary directions for this adjustment, which in many cases is very much better. If that is carefully done, the *E* readings will be diminished, and the *W* readings increased by 5.7", and they will stand thus:—

	<i>E.</i>	<i>W.</i>
In the first position	61.7	53.9
In the reversed position	53.9	61.7

or the bubble keeps the same position in its scale before and after reversing, and the axis is vertical to the line joining the two foot-screws. The bubble must be placed at the same divisions when over the third foot-screw, and the axis is truly vertical. The difference between the last-mentioned readings is 7.8", and the half of this, or 3.9", is the quantity through which the bubble should be moved by the level-screw to complete its adjustment, if that be desired; but if the true value of the divisions of the scale be known, and it is also known that this does not sensibly vary with the temperature or from other causes, it is useless to adjust very scrupulously, since the ends of the level must always be read and noted, and the difference allowed for by a careful observer. In some larger instruments of this construction, the vertical axis is adjusted by a plumb-line, which Ramsden and Troughton applied in different ways. One of these applications will be described under ZENITH SECTOR; but we are inclined to think that the ground-level is more accurate, while it is incomparably more convenient than the plumb-line, for small circles, which move freely in azimuth, and are used agreeably to their construction. The vertical axis being properly placed, the cross axis of the upper circle is next to be set horizontal. Pass the detached level carefully through the openings in the circle, place its notches on the pivots of the axis, note the ends of the bubble, exactly as before, reverse the level, and note the ends again. Suppose the results to be—

	East End.	West End.
First position	6.24	8.43
Reversed position	7.96	6.71
Mean	7.10	7.57

Hence the difference between the mean readings is 0.47, or the west end is higher than the east by 0.235. The bubble must be moved this quantity towards the east by raising the east or depressing the west pivot. There is a screw under each pivot for that purpose. It is convenient to have the scale divided into parts, of which the units are 15" of a degree.

The microscopes should be adjusted, if that be required, in the manner already described, but we recommend amateur observers, at least, to have the body of the microscopes made unalterable, after the maker has settled both the adjustments, by pinning together the body and tube which carries the object-glass. Both adjustments will then be performed by making the 5' spaces equal to five revolutions of the micrometer screw, simply by shifting the body of the microscope a little nearer to or farther from the instrument. This should be done pretty carefully, but any remaining error may be corrected as in the mural circle. The microscopes (there are generally a pair to each circle) are finally to be placed in a diameter of their respective circles, and nearly in the middle of the concentric lines, which contain the divisions. There are screws in the tubes by which the microscopes are mounted, which allow them a little motion in any direction, and the cross wires are thus brought to bisect divisions 180° apart. This requires no particular exactness, and may be done at once for the azimuth circle. The upper microscopes may be adjusted approximately. The optical part of the instrument must now be put into order. At the eye end of the telescope there are generally five or seven vertical and three or five horizontal wires, that is, fine lines of cobweb, raw silk, or any very delicate and uniform fibre. To place these in the focus of the object-glass, apply the highest magnifying power you have got, bring the wires to distinct vision, and look at a bright star. The wires and eye-piece are fixed on a piece of tube which moves stiffly within the tube of the telescope, and this must be pushed in or drawn out till the star is seen perfectly round and surrounded with rings, the wires being at the same time sharply defined. This adjustment may be completed or verified thus: The pole star, or any circumpolar star, may be bisected by the vertical wire when near

its greatest elongation, or by the horizontal wire when near the meridian. In the former case the eye is to be moved on each side, in the latter up and down; and if the star continues bisected, and there is no dancing of the star on one side or other of the wire, the position is correct. When the star moves contrariwise to the eye of the observer, the tube must be pulled out, as the image of the star is then formed between the wires and the eye, and the wires must be brought to the same place. When they move the same way, the tube is to be pushed in until the image is formed exactly upon the wire. Any error must be corrected by gradually pushing the tube in or out. When this has been once successfully done, a notch for verification should be made to save all future trouble. The vertical wires are now to be set at right angles to the axis. Take any well-defined object, either a sharp distant terrestrial mark, or the wires of a subsidiary telescope [COLLIMATOR], or a circumpolar star at its greatest elongation. Bisect this at the centre of the middle wire, and move the telescope up and down until you see the object at the top and bottom of the field. If it is not bisected there twist the moveable tube round, and so bisect it, and repeat the operation until you are satisfied. The middle horizontal wire, if a correct position of that is preferred, must be adjusted, by twisting the tube until a star on the meridian runs along the horizontal wire by its own motion, the azimuth circle being fixed; or by moving the instrument in azimuth after having bisected Polaris or a circumpolar star near the meridian, on that wire. There are screws above and below the tube at the eye end, which should now be tightened. To make the central and vertical wire describe a great circle, bisect a well-defined object, as near the horizon as may be, read the horizontal microscopes, turn the instrument 180° in azimuth, and observe again, reading the same microscopes. If the means of each pair of readings, before and after reversion, differ *exactly* 180°, the wire describes a great circle; if not, move the instrument half way to 180° by the clamp screw, and bisect the object by turning two antagonist and pulling screws near the eye-piece, which draw the wire plate to either side; repeat the operation until you are satisfied. If the horizontal clamp is strong enough, the circle may be taken out of its axis and reversed as an ordinary transit [TRANSIT]. The upper microscopes may now be correctly adjusted. Observe any object which does not alter its altitude on the middle horizontal wire, and read the upper microscopes; turn the instrument through 180° of azimuth, and observe the object again. Move the circle to exactly the middle of these two readings (which will be near either 0° or 90°), when the telescope is in the zenith, and then by the adjusting screws set the crosses of each of the microscopes exactly on 0° or 90°, as the case may be; the microscopes are then in a diameter, and the error of collimation in altitude is also destroyed. As this correction is altered by any alteration of the apparatus for levelling the horizontal axis, and as few observers like to meddle with the adjustments of their microscopes, the microscopes can be brought into a diameter after the axis is made horizontal by raising or lowering each of the levelling screws a small equal quantity; but though it is convenient that the microscopes should read nearly the same angle, it is not at all essential to accuracy, and the error of collimation must always be ascertained or eliminated by the mode of observation.

We shall always suppose every observation to be a *mean* of two, one made face east and the other face west, unless the contrary be said or implied. In this case there is no error of collimation.

The altitude and azimuth circle was, as has been stated, invented by Römer, though a quadrant moving freely in azimuth, and with a graduated horizontal circle, was used by Hevelius. It is the most universally useful of all astronomical instruments, and is both portable and accurate. In delicate hands, and with some power of calculation, it is capable of performing a great deal of good work. Besides being an excellent geodesical instrument [THEODOLET], it is, when placed in the meridian, an accurate, though not very convenient transit. It may be used in this position as a meridian or transit circle, for determining at once the right ascension and zenith distance of any unknown stars. In this case the horizontal point must be got by combining observations taken directly with others by reflection, in the manner already described in the mural circle; or else several standard stars may be observed, and their instrumental places compared with their computed places; the mean of these differences is to be applied as an index error to correct the observations of unknown stars exactly as in Mr. Pond's first method with the mural circle. In this mode of observing there is no reversion.

The principal merit in the altitude and azimuth circle is, that it can be moved in azimuth without injuring its accuracy as a measurer of zenith distance. Let us suppose a navigator in a strange place with such an instrument and a time-keeper, of which the error is unknown. This should mark sidereal time. The instrument must first be nearly adjusted, and the approximate meridian selected. This will be known near enough by shifting the instrument in azimuth till it is found that a star, which is bisected by the horizontal wire, continues to be bisected for a short time. Observe the zenith distance of some known star in this direction, and this will give an approximate latitude. The time and the azimuth of the star should also be noted. Now observe the zenith distance of another known star near the prime vertical, the time deduced from this and the approximate latitude will be a very close approach to the true sidereal time at the place. The

original latitude from the first observation may now be corrected by a more accurate knowledge of the time, and the azimuth of the star at the time of observation be deduced, whence the reading corresponding to the meridian position of the instrument is also known. If these observations have been managed with any skill or discretion, the latitude and time are now found near enough for future calculations.*

To ascertain the latitude with the utmost precision, several standard stars are to be observed near the meridian, and, if it may be, at pretty nearly equal distances from the zenith, north and south, to 70° or 80° zenith distance. A few minutes before the star comes to the meridian, bisect it near the centre of the middle horizontal wire, noting the time of bisection. It is perhaps more exact to place the wire close to the star, and then, leaving the vertical circle untouched, to move the whole instrument by the horizontal clamp along with the star, until it is bisected upon the wire by its own motion. The ends of the level and the upper microscopes are then read, the instrument is turned gently round 180° in azimuth, and the observation is repeated. The sum of the two angles (when each pair of readings is connected into one zenith distance) is twice the apparent meridian distance of the star, affected by the want of verticality in the axis, which is known from the level, and by a small correction depending on the time of observation. It is clear, that if the end of the level towards the eye end of the telescope is too high, the foot-screw towards the observer should be lowered, in which case the telescope would point above the star, that is, show a less zenith distance than the true zenith distance. Hence the rule is, take the reading of the end of the level towards the object end of the telescope from the reading towards the eye end, halve the difference, and add this, when converted into arc, to the instrumental zenith distance. This may be done in each case, or the mean of the whole applied to the mean of the instrumental zenith distance. For the *correction to the meridian* the formula is,

$$\text{Corr.} = \frac{\cos. \text{dec.} * \times \cos. \text{lat.}}{\sin. \text{zen. dist.} *} \times \frac{2 \sin. 2 \frac{1}{2} \text{ angle at the Pole}}{\sin. 1''}$$

The first factor must be computed for each star; the latter is taken from a table which may be found in *Schumacher's Hülfsstafeln*, or *Baily's Tables*, and in many collections of astronomical tables. The argument is the angle at the pole, that is, the difference between the moment of observation and the transit of the star. This correction is to be *subtracted* from the zenith distance of stars observed *above* the pole, and *added* to those observed *below* the pole. The mode of observing is generally known by the name of *circum-meridian*. We have here detailed the process as it refers to a single pair of observations, but several pairs may be taken, as many as can without hurry be got in a quarter of an hour on each side of the meridian. With a good instrument and a careful observer, the latitude thus deduced from several stars will be very near the truth, if the observer employs a correct catalogue, such, for instance, as that of 1112 northern stars, published by Mr. Pond in 1833, or the catalogue of southern stars, by Lieut. Johnson, 1835: if he can observe the same circumpolar stars at their upper and lower culminations, he may obtain a latitude independently of any catalogue. If stars near the pole be observed, it is not necessary that they should be near the time of passing the meridian, but the reduction to the meridian zenith distance must be computed by an exact formula. There are special tables of Polaris for this purpose in the *Nautical Almanac*.

The time may be found by two or three methods. The zenith distances of known stars near the prime vertical, both to the east and west, may be observed, and the horary angle computed from the observed zenith distance and the known colatitude already found. In this case the altitude circle should be kept clamped, while the times of the passage of the star over each of the horizontal wires are noted, the mean is to be taken, and the instrumental zenith distance is to be corrected for the indication of the fixed level. Repeat the operation after reversing the instrument, and take the mean of the zenith distances, which will correspond very nearly with the middle time between the observations. From this zenith distance the error of the time-keeper is found. The mean of the errors deduced from an equal number of stars on the east and on the west prime vertical will be very nearly correct, and depend upon the divisions of the circle and the catalogue employed. Also, the altitude circle being clamped, a star may be observed rising near the east prime vertical, and again, by moving the instrument in azimuth, near the west prime vertical when descending. The middle time will be the meridian passage of the star by the time-keeper, which, when compared with the computed right ascension, will show the error of the time-keeper. This method (commonly called that of *equal altitudes*) is not to be recommended, except for stars near the zenith, which pass quickly from one prime

* Let S be the first star observed near the meridian, and σ the second near the prime vertical, r the pole, and z the zenith; then Pz the colatitude = $Ps - zs$ nearly. Again, the triangle $Pz\sigma$ being solved with this approximate value of Pz will give the angle σPz , which, if the star is west, being added to, or if east, being subtracted from its right ascension computed from the catalogued place, gives the true sidereal time at the place of observation, and hence the error and correction of the time-keeper. Let this correction be applied to the time of observing s , then the difference between the time so corrected and the computed right ascension of s gives the $\angle \sigma Pz$, from which the correction of zs to the meridian may be deduced.

vertical to the other. The changes of the level, of the instrument, or of the time-keeper, may occasion greater errors than can well arise from the divisions of the circle, not to mention the greater length of time occupied by the observation, and the chance of disappointment from change of weather. Lastly, the time may be derived from this instrument, when the lower circle is clamped, and the telescope is made to move in the meridian like a transit. The transit will be explained hereafter, but the adjustment to the meridian is greatly facilitated in this instrument by the divided horizontal circle. Either the azimuths of a star may be observed when it has the same altitude on the east and west of the meridian, in which case the middle reading of the azimuths will be the reading corresponding to the meridian; or the time may be got very nearly from a star near the zenith, and then the error of the time-keeper being known, Polaris or any near circumpolar star, may be bisected, by moving the instrument in azimuth, at the time when, by the clock, it should be on the meridian; or Polaris, or any known circumpolar star, may be observed at its greatest elongation, when its azimuth is known by computation; or, generally, a known circumpolar star may be observed anywhere, and its azimuth be computed for the *known* time of the observation, when the instrument can be shifted this quantity. For the mode of correcting errors of level, &c., and of deducing the longitude from the passage of the moon over the meridian, &c., see TRANSIT.

When the direction of the meridian is required with great accuracy, the process used in the 'Trigonometrical Survey,' vol. i. p. 242, may be followed. The azimuth of Polaris was observed when at its greatest elongation to the east and to the west of the meridian, and the mean of these was taken for the reading of the north point. The cross level should be applied to the transit axis and the error carefully noted before every observation, and the instrument should be reversed once at least during the series.

Little has been said of the *error of collimation in altitude*, because in truth the determination of this error is scarcely ever required in a separate shape by an accurate observer. It may, however, be determined thus: Observe a star with the divided face of the circle to the east, and then with face west, near the meridian, exactly as has been already described, correct each zenith distance to the meridian and for the indication of the fixed level. Then the difference between these zenith distances, if any, shows that the microscopes do not read 0° , when the telescope is in the zenith and the vertical axis is correct: half the difference is to be added to all observations made with the instrument when the face is one way, and to be subtracted from all observations when the face is the other way, as the case may be.

If an observer should wish to use an instrument of this kind for making a catalogue of unknown stars, he may place it accurately in the meridian, and observe transits and zenith distances at once, using an index error for the latter, deduced from known or standard stars, as we have described above. Or the zenith distances may be determined by *circum-meridian* observations, which is perhaps a more accurate and certainly a more independent mode. The peculiar advantage of the altitude and azimuth circle is, however, for observing phenomena when out of the meridian, and therefore not within the reach of the principal instruments: for instance, in determining the place of a comet, &c. Here the time must be noted when the object is bisected by the crossing of the horizontal and vertical wires, and the upper and lower microscopes and fixed level read off. The instrument is now to be reversed and the operation repeated. Then if the object is not near the meridian and the interval is short, the mean of the zenith distances and the mean of the azimuthal readings correspond very nearly to the middle time, and as the azimuthal reading of the meridian is, or easily may be known, the azimuth and zenith distance of the object at a *given* time are known, which, with the colatitude, are two sides, and the included angle of the triangle ZPS , which can therefore be solved, and the polar distance PS , and the horary angle ZPS be found. If the observations should be made near the meridian, the corrections as found in circum-meridian observations must be applied.

The observer, who is not afraid of working spherical trigonometry, will find the following a very exact method of ascertaining the place of a comet or planet: Observe the altitude and azimuth, noting the time, of a known star, as near the comet as may be, and then the altitude and azimuth, also noting the time, of the comet. The *computed* altitude and azimuth of the star, when compared with that *observed*, will give an index error for the instrument, in altitude and in azimuth; which, when applied to the observed places of the comet, afford correct data for computing its horary angle and polar distance. This method is only an application of the principle of measuring differences, rather than absolute quantities, and admits of great exactness, even with an indifferent instrument, especially if several stars, on different sides of the comet, are used; but the labour is considerable.

An instrument of this kind will show very clearly the effects of refraction and parallax, though it cannot be expected to increase our knowledge on these points. On comparing the observed zenith distance with the zenith distance computed from the polar distance, and the horary or azimuthal angle, the difference will be the effect of refraction, or of refraction and parallax, as the case may be. The determination of the law and quantity of refraction was one of the purposes for which Piazzi's circle was principally designed.

The instrument-maker ought to mark the value of the parts on the

scales of the levels, but it is advisable to ascertain these independently. Place the instrument so that the third foot-screw, that with the slow motion apparatus, is in the plane of the altitude circle, raise the foot-screw till the end of the bubble towards the observer is near the end of the scale, bisect a well-defined object with the telescope, and read the upper microscopes and the ends of the bubble. Then lower the foot-screw till the bubble is towards the other end of the scale, bisect the object again, and read off the microscopes (bringing the crosses to the same divisions) and bubble as before. You have thus a given number of parts of the scale, those through which the bubble has travelled equal to the difference of the readings of the microscopes in the two positions, which is therefore known in seconds of spaces. This should be done several times, and the temperature noted, as it will be found that not only the length of the bubble, but the value of the parts, varies with the temperature. A table may then be made for future use. By attaching the cross level to the altitude circle it may be examined in the same way.

There are several variations in the form of the altitude and azimuth circle. The vertical axis is sometimes depressed below the azimuth circle, which gives the instrument a greater compactness of form. In a few instances, instead of a pair of microscopes upon a fixed support, there are three or more which can be placed anywhere on the circumference of a ring, parallel to and concentric with the vertical circle. This is a very essential improvement, as besides getting rid of eccentricity, three microscopes at 120° distance, or a pair at right angles, destroy the effect of any change of figure corresponding to ellipticity. (See 'Monthly Notices of the Astron. Soc.,' vol. ii. p. 96.) The errors of division may also be gradually eliminated by changing the positions of the readings. Three or more microscopes are sometimes applied to the horizontal circle.

The circle here drawn and described is divided by an engine; in instruments of higher pretensions one or both circles are divided by hand, generally according to Troughton's method. Sometimes both faces of the vertical circle are divided. There is a figure and description of a very beautiful circle, generally known by the name of the Westbury circle, in a paper by Mr. Pond, 'Phil. Trans.,' 1806, p. 420, plate xx., and of another in Pearson's 'Astronomy,' vol. ii. p. 434, plate xix. A vertical circle, of eight feet diameter, moving freely in azimuth, planned by Ramsden and finished by Berge, is at the Observatory of Dublin, which, so far as we know, has not yet been described, though well known by the deductions of Dr. Brinkley. (See 'Trans. Royal Irish Academy,' vol. xii. p. 33.)

The *transit circle* is very shortly described, as it is only the upper circle of the last-mentioned instrument, generally on a larger scale. This, when fixed in the plane of the meridian, may be used both as a transit and as a meridian circle at the same time. The supports should be of stone, to which the reading microscopes should also be attached. A very beautiful transit circle, of four feet diameter, and divided on both faces, was constructed by Mr. Troughton in 1804. This was for many years in the possession of the late Stephen Groombridge, Esq., of Blackheath, and was employed by him in forming a catalogue of stars within 50° of the north pole. It is described and engraved in Pearson's 'Astronomy,' vol. ii. p. 402, plate xvii. The artist himself was dissatisfied with the weakness of the axis, a capital fault in an instrument for observing transits; and we conceive that there was a still greater oversight, though one more easily repaired, in the unsteady fixing of the reading microscopes, which are mounted on slender bars of brass instead of stout stone crosses; the consequence was, that the index error was always changing. The meridian circle of Röemer, and those which resemble it, have been already mentioned. This form is perhaps preferable to that of Groombridge's, the axis being less subject to flexure; but its unsymmetrical appearance is disagreeable, and make some of the ordinary modes of adjustment impracticable. The unequal bearing on the pivots may also require caution. The meridian circle of Reichenbach is like the ordinary transit telescope, with the circle and verniers close to one of the pivots. It is too complicated to be described in a few words, and is not, we believe, to be met with in this country; but most of the Continental observatories east of the Rhine are furnished with them. In the hands of Bessel, Gauss, &c., the circle of Reichenbach is undoubtedly a very powerful and accurate instrument; but we think not so perfect, certainly not so fit for ordinary observers, as a closer copy of Röemer's would be, while it is much less simple, and the telescope is more liable to injurious flexure.

The adjustments of the transit circle are those of a mural circle and of a transit combined. A very ingeniously contrived plumb-line was applied to Groombridge's circle, to level the cross axis and adjust the collimation in altitude; but the methods already described were found to be more accurate and much less troublesome. Indeed, the plumb-line apparatus of the mural circle is superseded by the use of observations by reflection.

* In 1851 the mural circle and transit instrument of the Royal Observatory, Greenwich, were replaced by a transit circle, the design of which is due to Mr. Airy, the present astronomer-royal. This fine instrument was constructed by Messrs. Ransome and May, of Ipswich, and Mr. Simms, of London. The telescope has an aperture of 8 inches, and a

* This paragraph and the one which follows has been added to the original article by the Rev. Richard Sheepshanks.

focal length of $11\frac{1}{2}$ feet. The circle is 6 feet in diameter. The divisions are read off by means of six microscopes firmly imbedded in stone piers. The material used in the construction of the instrument is cast-iron. A similar instrument has been subsequently made by Mr. Simms, for the Royal Observatory at the Cape of Good Hope. The transit-circle used by Mr. Carrington in the observation of the stars for his Redhill catalogue, has also been constructed upon the plan of the Greenwich instrument.

An altitude and azimuth circle has been recently introduced at the Royal Observatory, Greenwich, for the special purpose of observing the moon when she is out of the meridian. Two distinct circumstances suggested the expediency of this step. In the first place it frequently happens, that when the moon is on the meridian she is concealed from observation by the unfavourable state of the weather; secondly, the moon cannot be seen on the meridian for several days before and after conjunction, by reason of the overpowering effulgence of the sun's rays. By means of the altitude and azimuth-circle, or the altazimuth as it has been called, this inconvenience has been effectually obviated, the number of extra-meridional observations being about twice as great as the number of observations made when the moon is on the meridian. The altazimuth was designed by Mr. Airy, and constructed by Messrs. Ransome and May of Ipswich, and Mr. Simms of London. The vertical and azimuthal circles are each 3 feet in diameter. The telescope is furnished with an object-glass of $3\frac{3}{4}$ inches aperture. The observations with this instrument were commenced on the 16th of May, 1847. A remarkable illustration of their utility in contributing towards the improvement of the lunar theory, has been recently afforded by a comparison of the meridional and extra-meridional observations of the moon made at the Royal Observatory, Greenwich, in the year 1852, with the corresponding results of 'Burckhardt's and Hansen's Lunar Tables.' ('Monthly Notices, R. Ast. Soc.' vol. xix. p. 211, *et seq.*) The agreement of the observed places of the moon with Hansen's Tables' (in the preparation of which the extra-meridional observations of the moon were used) leaves nothing to be desired.

Besides the works we have already referred to, the astronomical reader may consult, as to the mural circle, Pond's 'Observations,' 1812, p. 236, and 1825 (where an example is fully worked out), for an account of his two methods, and his memoirs in the 'Phil. Trans.' and 'Memoirs of the Astronomical Society'; 'Cambridge Observations,' vols. vi. and vii., and Johnson's 'Catalogue of Southern Stars,' 1835. For the transit circle, Wollaston's 'Fasciculus,' preface and appendix. For the altitude and azimuth circle, a paper by Mr. Troughton, 'Memoirs of the Astron. Society,' vol. i. p. 33; and generally, the article 'Circle' of the 'Edinburgh Cyclopædia,' by Mr. Troughton, and Dr. Pearson's 'Practical Astronomy.' On the mode of dividing circles and the errors to which their divisions are liable, see GRADUATION, and Troughton 'Memoir, Phil. Trans.,' 1809, p. 105; Dr. Robinson's Paper, already cited, and another by the same author, 'Memoirs of the Irish Academy,' 1825; two Papers in the 'Memoirs of the Astron. Society,' on the 'Errors of the Cape Circle,' one by Mr. Sheepshanks and Professor Airy, vol. v. p. 320; the other by Mr. Henderson, vol. viii. p. 141.

CIRCLE, MURAL. [CIRCLE, ASTRONOMICAL.]

CIRCLE, QUADRATURE OF THE. [QUADRATURE.]

CIRCLE, REFLECTING. [SEXTANT.]

CIRCLE, REPEATING. [REPEATING CIRCLE.]

CIRCLE, TRANSIT. [CIRCLE, ASTRONOMICAL.]

CIRCLES OF DECLINATION, ALTITUDE, &c. The use of these terms is not very well settled. According to some, a circle of declination would mean the parallel of any declination, or the small circle all whose points have the same declination; that is, a parallel to the equator. According to others, it would mean the circle on which declination is measured, that is, an *horary* circle passing through the poles. And the same of the other circles. Perhaps the latter sense is the more generally used; but in all cases the student must be aware of the difference when he consults a book on the doctrine of the sphere.

CIRCUITS, in English law, denote the periodical progresses of the judges of the superior courts of common law through the several counties of England and Wales, for the purpose of administering civil and criminal justice. The ordinary circuits take place in the spring and summer of each year; and for several years past the judges have made winter circuits through the principal counties in the month of December, for the trial of criminals. In 1858, the experiment of a Winter Assize for civil business was tried at Liverpool. All the circuits take place under the authority of several commissions under the great seal, issued to the judges and others associated with them on each occasion. [ASSIZE.] Most barristers practising in the common law courts in London are attached to one or other of the circuits; and each circuit is constantly attended by a numerous bar. The transaction of judicial business in the presence of a professional audience of this kind, has been justly considered as one of the best securities for the due administration of justice; and in consequence of the system of circuits, this advantage is not confined to the metropolis, but is communicated to the most remote parts of the kingdom.

Since the statute 11 Geo. IV. and 1 Will. IV. c. 70, by which the ancient system of Welsh judicature was abolished, the circuits of the judges are eight in number, and the counties of England and Wales

are distributed among them in the following manner: The Northern Circuit comprehends the counties of York, Durham, Northumberland, Cumberland, Westmoreland, and Lancaster; the Western Circuit comprehends the counties of Southampton, Wilts, Dorset, Devon, Cornwall, and Somerset,—and Bristol; the Oxford Circuit comprehends the counties of Berks, Oxford, Worcester, Stafford, Salop, Hereford, Monmouth, and Gloucester; the Midland Circuit comprehends the counties of Northampton, Rutland, Lincoln, Nottingham, Derby, Leicester, and Warwick; the Home Circuit comprehends the counties of Hertford, Essex, Kent, Sussex, and Surrey; the Norfolk Circuit comprehends the counties of Buckingham, Bedford, Huntingdon, Cambridge with the Isle of Ely, Norfolk, and Suffolk; the South Wales Circuit comprehends the counties of Glamorgan, Carmarthen, Pembroke, Cardigan, Brecon, Radnor, and Chester; the North Wales Circuit comprehends the counties of Montgomery, Merioneth, Carnarvon, Anglesey, Denbigh, Flint, and Chester.

CIRCULAR PARTS (NAPIER'S). A proposition which generalises the relations between the parts of a spherical right-angled triangle into two only; first given (with a demonstration) by Napier in his 'Mirifici Logarithmorum Canonis Descriptio' (ch. iv. 1-8). It is as follows: Let a and b be the sides, c the hypotenuse, and A and B the angles opposite a and b , in a right-angled spherical triangle. Then take the complements of the hypotenuse and of the two angles, and the two sides, and write them in order in a perpetually recurring series, or round a circle, as follows:—

Then taking any three parts, one may be made the *middle* part, and the other two either *adjacent* extremes, or *opposite* extremes. Thus $90^\circ - B$ being the middle part, a and $90^\circ - C$ are its adjacent extremes, and b and $90^\circ - A$ its opposite extremes. Napier's rules are

1. Sine of *middle* = product of tangents of *adjacents*.
2. Sine of *middle* = product of cosines of *extremes*.

$$\text{Thus } \sin. b = \tan. a \tan. (90^\circ - A)$$

$$= \cos. (90^\circ - B) \cos. (90^\circ - c).$$

But we should strongly recommend the student to have nothing to do with this artificial memory, for it involves a process upon every occasion; and while one person is learning which are the parts, which have complements taken, and the rules, another will master the six results, and will have no occasion for any future process. These results are

1. Cosine of hyp. = product of cosines of sides.
2. Cosine of hyp. = product of cotangents of angles.
3. Sine of *side* = sine of hyp. $\times$ sin. *opposite* angle.
4. Tang. of *side* = tang. of hyp. $\times$ cos. *adjacent* angle.
5. Tang. of *side* = tang. *opposite* angle $\times$ sine of other side.
6. Cos. of *angle* = cos. of *opposite* side $\times$ sin other angle.

These pairs present analogies which will help the memory, and we should recommend them in preference to the rules of circular parts.

CIRCULAR POLARIZATION. [ROTATORY POLARIZATION.]

CIRCULATING DECIMALS. When a common fraction cannot be expressed exactly as a decimal, the attempt leads to a never-ending series of figures, any number of which, with the decimal point properly placed, is an approximation to the common fraction, and the more near the greater the number of figures taken. Thus 1 with ciphers affixed and divided by 7, leads to the recurring or circulating series

$$142857142857142857 \dots$$

and $\cdot 1428$ is nearly $\frac{1}{7}$, but $\cdot 14285714$ much more nearly. Hence it is said that $\frac{1}{7}$ is a circulating decimal whose period is 142857, and is denoted by $\cdot 142857$. Similarly $\cdot 129$ denotes $\cdot 129999 \dots$ and $\cdot 0536$ denotes $\cdot 053636 \dots$. As a part of fractional arithmetic, the rules for converting these fractions into common fractions are useless, though found in most elementary works. One example will be sufficient here.

$$\cdot 14362 = \cdot 14362362, \&c. = \cdot 14 + \frac{1}{100} \times \cdot 362362 \dots$$

If the circulating part continued *ad infinitum* be called *S*, it is plain that $1000\ S = 362 + S$, or $S = \frac{362}{999}$, whence

$$.14362 = \frac{14}{100} + \frac{362}{99900} = \frac{14 \times 999 + 362}{99900}$$

Wallis ('Algebra,' ch. 89), Euler ('Algebra,' ch. 12, book i.), and John Bernoulli the second ('Mem. Acad. Sci.' 1771), have treated this subject. We shall merely state some theorems to show the remarkable character of the periods.

1. Form the period of a prime number m ; its number of figures will be either $m-1$ or one of its divisors. The period of 7 (being 142857) has six figures; that of 13 (being 769230) has 6, the half of $13-1$ figures.

2. When the period of a prime number m contains $m-1$ figures, the last half may be formed from the first by taking each figure in the first from 9. Thus the first and second halves of the period belonging to 47 are—

First half 02127659574468085106382
Second half 97872340425531914893617

3. When the period of a prime number m has $m-1$ figures, multiplication by any number under m only changes the order of the figures. Thus the period of 7 being 142857, we have here a number which, being multiplied by 2, becomes 285714; by 3, 428571; by 4, 571428; by 5, 714285; and by 6, 857142.

The following work may be useful to those who are curious on the subject: 'A Table of the Circles arising from the division of a Unit, or any other whole number, by all the integers from 1 to 1024, being all the pure decimal quotients that can arise from this source.' London, Richardson, 1823.

CIRCUMCISION, the operation of cutting off the prepuce or foreskin, is sometimes performed for a medical purpose; but it is general or universal among some nations as a religious rite, and among others as a national custom. The practice of circumcision appears to be of the highest antiquity. Abraham, as recorded in Genesis (xvii. 10-14), by the command of God, circumcised himself and all the males of his household; though circumcision is not there mentioned as being a novelty, nor are any directions there given for the manner of performing the ceremony. Abraham himself was ninety-nine years old (Gen. xvii. 24) when he was circumcised. The rite of circumcision was ordained to be an everlasting covenant between God and the seed of Abraham; and it was declared that "the uncircumcised man-child whose flesh of his foreskin is uncircumcised, that soul shall be cut off from his people; he hath broken my covenant." All the males that left Egypt were circumcised, but during the forty years' wandering in the wilderness the rite was not performed. Joshua, by the express command of God, renewed it by circumcising all the males just after the passage of the Jordan. (Joshua v.) Ever since the circumcision by Joshua, it has been universally observed, both among the Jews and the Ishmaelitic descendants of Abraham. Circumcision is not, properly speaking, a rite of the Mohammedan religion; it is not enjoined in the Koran, but the Arabs, and Mohammed himself, were circumcised before the religion of the Koran began to be preached, and their descendants have continued the usage as one which had always prevailed among them, and have also communicated it to the Saracens, the Turks, and the other nations who have become associated with them in a common faith. In point of fact, circumcision is as universal among the Mohammedans as it is among the Jews.

A great deal has been written, both on the ceremonial of the Jewish circumcision, and on the question as to the sacramentary efficacy which has been sometimes attributed to the rite. On these matters the reader may consult Burder's 'Oriental Literature,' Calmet's 'Dictionary of the Bible,' Simon's 'Dictionary of the Bible,' and especially the able dissertation on circumcision in Michaelis's 'Commentaries on the Laws of Moses,' book iv. chap. iii. part i., the English translation by Dr. Smith, 4 vols. 8vo, 1814, and the authorities there referred to. Michaelis is decidedly of opinion that circumcision was never intended as a sacrament. Among the ancient Jews, not only all proselytes were circumcised, but also all bondmen or slaves, and their children. (Gen. xvii. 12, 13.)

The prevalence of circumcision among various ancient nations is mentioned by Herodotus (ii. 36, 37, 104), by Diodorus Siculus (i. 26 and 55, iii. 32), and others. Herodotus says that the Colchi, the Egyptians, and the Ethiopians, were the only nations who had practised the custom from time immemorial, and that the Phœnicians and the Syrians of Palestine (the Jews) admitted that they had acquired the custom from the Egyptians. This notion, that the Jews had learned circumcision from the Egyptians, has been taken up and maintained in modern times by Sir John Marsham in his 'Chronicon Canon Aegyptiacus,' by Jahn, and others. (See De Pauw's 'Recherches Philosophiques sur les Américains.') But supposing this opinion to be false, it does not follow, on the other hand, as has been contended by some, that all other nations among whom the custom prevails must have derived it from the Jews. It has been supposed by some critics (but in our opinion without good reason), that among the ancient Egyptians it was only the priests, and those who desired to study the sciences of

which they were the teachers, who were obliged to be circumcised. See the notes of Wesseling and Larcher on the passages of Herodotus above referred to, the Commentary of Origen on the 'Epistle to the Romans,' ch. ii. v. 13, and a curious note of M. Huet on Origen's Commentary on Genesis. (Origenis Opera, à Car. de la Rue, 4 vols. fol., Par., 1733, &c., vol. ii.) It is said that Pythagoras submitted to the operation of circumcision in order to obtain instruction in the secret doctrines of the Egyptian priests.

Strabo (book xvii. 824) says by mistake that the Jews practised excision on their female children; but, although this never was a custom of the Jews, it has prevailed, and still does, among other nations, particularly the Abyssinians, Nubians, and the modern Egyptians. See Ludolphi, 'Hist. Æthiopica,' Niebuhr's 'Description de l'Arabie,' Sonnini's 'Travels in Egypt,' 'Description de l'Égypte,' and Browne's 'Travels in Africa, Egypt, and Syria.' The practice seems to have extended from south to north, and to have included Ethiopia, Egypt, Judæa, Phœnicia, Syria, Cappadocia, the Macrones, and the Colchians.

It is remarkable that circumcision has been found to prevail, and in some cases the excision of females also, among various savage or imperfectly civilised races. It is said that the rite was practised by the Mexicans when the Spaniards first became acquainted with them. Cook found an imperfect species of circumcision, consisting of the splitting of the prepuce, in use among the natives of the Friendly Islands. (Kerr's 'Voyages,' vol. xiii.) Long before, many of the old voyagers had met with it among the islands of the Indian Archipelago, among the tribes of the west coast of Africa, and elsewhere. In Purchas's 'Collection,' Edmund Scot gives a long account of the ceremonial of the circumcision of the king of Bantam in Java, at which he was present, in 1605. Captain William Keeling, in 1608, states that he found the people at the bay of St. Augustine, on the west coast of Africa, circumcised; and Captain Richard Jobson describes the ceremony, as he witnessed it at Batto, on the same coast, in 1621. An abstract of these and other early accounts may be found in Prevost's 'Histoire Générale des Voyages.' See the same work for a description of the ceremony of circumcision as practised among the people of Madagascar. Dampier, in his graphic manner, describes the mode of circumcision as he witnessed it performed in 1686 at the Philippine Islands. ('Voyages.') An account of what he calls the circumcision of females as well as of males by some of the African tribes, is given by Bosman, in his 'Description of the Coast of Guinea,' English translation; and it has been more recently ascertained to have long existed among some of the Indians in South America, among the inhabitants of Tahiti, and those of the Fiji islands. The principal distinction between circumcision as practised by the Jews and by other nations, is that the former, in obedience to the terms of the command given to Abraham, always when it is practicable circumcise the child on the eighth day after its birth; whereas, among other nations it is usually deferred to a much later period. Among the Mohammedans it is commonly performed in the thirteenth year, because Ishmael, the progenitor of the Arabs, was of that age when he underwent the operation. (Gen. xvii. 25.) By some it has been contended that this operation has been adopted from a notion that it was conducive to health in hot climates.

Kolben, in his 'Present State of the Cape of Good Hope' (translated by Medley), gives an account of a very singular custom of the Hottentots, which he conjectures may have been derived from the Jewish circumcision; and see Winer's 'Biblisches Realwörterbuch,' article 'Beschneidung,' Leipzig, 1847.

CIRCUMFERENCE (*circum* and *fero*), the line which goes round a figure. We do not know why, but this word is always applied to a curvilinear figure; while the synonymous Greek word periphery (*περί*, *φέρω*) is used for a rectilinear figure.

CIRCUMFERENTOR. This instrument is a species of surveying-compass, and its construction may be understood from a view of the diagram in the article SPIRIT LEVEL, since, if the reader will imagine the telescope of that instrument to be removed, and, for the supports, called Y.s, sight-vanes or perforated plates to be substituted, the instrument will be a complete circumferentor.

Such an instrument being far inferior to a theodolite in respect of the accuracy with which by its means a survey may be made, is not much used in Europe; but in the United States of America and in the British colonies, where land is less valuable, it is, or was till lately, almost the only instrument employed.

In using the circumferentor for the survey of a line of road, or the determination of the boundary of a tract of land, the instrument is set up, on its stand, successively at the principal bends of the road or boundary line; and a staff being held up vertically at the next bend which is visible from the place of the instrument, the sights of the latter are directed to it; then the bearing of each station-line from the needle in the compass-box, that is, from the magnetic meridian, is observed. Each station-line is measured by the chain, and the smaller bends of the road or boundary are determined by "offsets" measured perpendicularly to that line. [COMPASS, AZIMUTH; SURVEYING.]

CIRCUMFLEX. [ACCENT.]

CIRCUS, a large enclosed space, adapted for chariot-races, an amusement to which the Romans were passionately attached. The name Circus (of which circulus, a *circle*, is a diminutive) does not convey an

exact idea of the form of this building, which both in its outline and its use very much resembled the Greek Stadium. There were many circi in Rome, of which the Circus Maximus and the Circus Agonalis were perhaps the largest. The former may still be distinctly traced; the latter retains its external form only in the Piazza Navona of Rome. The Circus Aurelianus, or, according to some, of Heliogabalus, stood near the Amphitheatrum Castrense. The ruins of the Flaminian Circus are hid beneath the pavement of the city. The Circus of Nero was begun by Caligula; part of its site is now occupied by the Basilica of St. Peter. This circus is said to have been longer than the cathedral

Section of Seats.

Amphora used in constructing the arch.

[Plan of the Circus of Caracalla.]

Bianconi makes the Circus of Caracalla 255 French toises long, and 50 toises wide; the spina 142 toises long, and the start from the carceres to the spina 79 toises. The widths of the openings between the spina and the walls of the circus are 21·3 toises at the first goal, 19·3 at the second goal, 17 toises at the turn on the other side of the second goal, and 15·4 toises at the final goal. The width of the vaulting is 4 toises. (A toise is about 6·396 English feet.)

and colonnade in front. (Fontana's 'Tempio Vaticano,' p. 245.) Another circus, begun by Nero and finished by Hadrian, was situated in the gardens of Domitian, near the Mausoleum of Hadrian. Several

columns with statues on their summits, and altars, adorned the intermediate spaces between the centre and the goals; so that the spina must have presented a highly decorated and very pleasing appearance. The Porta Triumphalis, or gate by which the victor left the circus, was at the end opposite to the carceres. It is not improbable that the pulvinar, or emperor's seat, which in the Circus of Caracalla was a loggia with columns, was constructed at that part of the circus where the emperor, being near the carceres, would have the best view of the

antiquities and paintings were discovered here some years ago. In the Gardens of Sallust there was a fine circus, which was also adapted for the exhibition of naumachiae. The Circus of Flora was on the Quirinal Hill. There is a circus, not far from the Appian Way, near the tomb of Cæcilia Metella, about two miles from Rome, in a high state of preservation. It is probably of a later date than many of those which were constructed within the city; and perhaps to the circumstance of its being at a distance from the city walls, its present state of preservation may principally be owing. Antiquaries have called it the Circus of Caracalla, although no proof, we believe, has been discovered from inscriptions that this is the circus built by, and commemorated on the coins of, that emperor.

The Circus of Caracalla, of which we have given a plan and a section of the seats, may be considered a perfect model of this kind of building, both in judicious arrangement and ingenious construction. The long sides are not quite parallel: one end is semicircular, and the carceres at the opposite end, from which the chariots started, are formed on a segment of a circle, the chord of which is inclined to the long sides of the circus. The spina or raised division, which runs along the middle of the circus, is a kind of podium or basement, in appearance like a thick dwarf wall. It is not exactly parallel to either side of the circus. Of the carceres, which are twelve in number, six are placed on each side of the entrance which was intended for the use of the processions, and are so disposed, by the inclination of the chord line of the segment on which they may be said to be set off, that the starting of the twelve chariots was equalised. The carceres were most probably covered; they were also divided by partition walls with terminal figures in front of them, and arched over, with a cornice above the arches: the semicircular opening was filled with a window frame of marble, highly enriched; and they were closed with gates, most probably of bronze. A very tolerable idea of the architectural appearance of a circus may be formed from the inspection of a bas-relief in the British Museum.

There is also a representation of a marble fragment in Bianconi's work on this circus, in which men are seen opening the bronze gates, in order, as we may judge from their hurried action, to let out the chariots at the given signal. The spina, which was rounded at the two extremities, was decorated with metæ, or goals, each formed of three long cones: these cones are represented in the cut of a chariot race in the article CHARIOT, col. 759. Conical bells, called from their shape eggs (*ova*), were placed on the apex of each cone, and served to number the rounds which had been run. Dolphins were also employed for this purpose; these cones were sometimes gilt. In the basement of the cones in the Circus of Caracalla there is a small chamber formed; and the basements are separated from the spina. In the centre of the spina there was sometimes one of those enormous obelisks which were brought by the emperors from Egypt. Previous to the time of Augustus, a long pole occupied the centre. Small temples, statues

Circus of Caracalla were two towers, in one of which was a staircase leading to the roofs of the carceres. The people occupied the stone seats along the sides and at the semicircular end of the circus. The Euripus, a canal ten feet wide and ten deep, was formed as a protection to the spectators, when they were not separated from the open space by a high podium or basement. The Circus of Caracalla has the podium and no Euripus. Some notion of the appearance of the circi may be collected from the medals of Caracalla and Trajan. In these

medals the metæ and the quadrigæ are discernible, and the obelisk in the centre of the spina.

In order to lighten the weight of the materials used in the construction of the arch which supports the seats of the Circus of Caracalla, large amphoræ have been employed in the crown of the arch. Under this archway the people passed to the various openings with steps which led to the seats. The archway formed one great vomitorium. Although there were twelve carceres, the number of chariots varied; in a representation of a chariot-race on a sepulchral monument at Foligno, nine are represented.

The Circus Maximus, which was situated in a valley between the Palatine and Aventine hills, was very similar in form to that of Caracalla. According to Venuti, it was 210 French toises long by 85 wide,—that is, 1343·160 feet by 543·2; but other authorities have made the dimensions much greater. To Tarquinius Priscus tradition assigned the first building of a circus, on the site of which the Circus Maximus was afterwards erected. If ever there was a Circus of Tarquin, it may have been rebuilt after the destruction of the city by the Gauls. This edifice, whatever may have been its origin, was enlarged by Cæsar, and embellished by Augustus and Tiberius. In the time of Nero it was burnt down (Tacit., 'Annal.' xv. 35); Trajan repaired it; and under Antoninus it became partially ruined, but was afterwards restored. The exterior of the circus, except at the carceres, consisted of two stories, adorned with columns, and finished with a terrace. The ground floor was occupied by merchants, except on the days appointed for the games. There were four towers more in the Circus Maximus than in that of Caracalla; one in the centre over the carceres (equidistant from those at each end of the carceres), one over the principal entrance, and one at each end of the semicircle, where it joined the straight sides of the circus: these towers were crowned with quadrigæ. The spina, which was rather more than 8 feet high and 12 broad, was decorated with temples in miniature, statues, and obelisks. Augustus brought an obelisk from Egypt, 126 feet high, and placed it in this circus; Constantius also erected in the circus the obelisk now called the Lateran, which is the largest of all the Roman obelisks.

There are traces of a circus at Tarragona, at Merida, at Murviedro (the ancient Saguntum), all in Spain; also at Nismes, Milan, Antioch, at Constantinople, and other places.

The games, which derived their name, *ludi Circenses*, from the circumstance that, after the time of Tarquinius, they were celebrated in the circus, were, according to tradition, instituted by Romulus

under the name of Consualia (Livius, i. 9), in honour of the god Consus (or Neptune). They were exhibited on various occasions and for various purposes; sometimes, for example, by magistrates and sometimes by private citizens; either as rejoicings for success in war, or to avert the anger of some god. A grand procession from the capitol to the circus opened the games, and the images of the gods were taken along in carriages (*thensæ*). The combatants, dancers, musicians, and others followed, and last of all the consuls and priests advanced to perform the sacred rites. The exhibition consisted chiefly of chariot and horse races. The charioteers were divided into four classes, distinguished by the colour of their dress; one was white, another red, another sky-coloured, and another green. Domitian added two more, the golden and the purple. The favour of the people to one class or another was determined quite as much by the dress as by the skill displayed. Serious consequences often followed the disputes on the superiority of one colour above another. The order in which the chariots stood was determined by lot; and the signal for starting was given by dropping a cloth (*mappa*, or *pannus*). The chariot which first ran seven times round the course was victorious; and the driver, after being proclaimed by the herald, was crowned with a palm-wreath, and received a considerable sum of money. There were usually twenty-five such heats in the course of a day. Contests in the five exercises (*quinquertium*, the Greek *πένταθλον*), running, leaping, boxing, wrestling, and throwing the discus, also formed part of the exhibition. Wrestlers were anointed with ointment by slaves; boxers used gloves strengthened with lead or iron to give force to their blows; all underwent a preparatory training and dieting. These exercises were performed by the combatants almost entirely naked, and hence were called sometimes *certamen gymnicum*; the combatants had only a slight covering round the middle. A mock fight, called *ludus Trojæ*, was performed by young noblemen on horseback, an exhibition which was revived by Julius Cæsar. (Virgil, 'Æn.' v. 561.) A sea-fight (*naumachia*) was sometimes represented: Domitian afterwards built a sea-fight theatre. (Suetonius, 'Domit.' c. 5.)

The exhibition of the wild beasts (*venatio*) was one of the most attractive parts of their public entertainments. Wild beasts fought either with one another or with men; and the men were either forced to this combat as a punishment, or were induced to enter it by hire. Great expense was incurred to provide beasts for this exhibition, and

they were collected from the most remote parts of the empire. In the days of imperial splendour and profusion, the public exhibitions of Rome contained nearly every rare wild animal that western Asia and northern Africa could produce. The beasts were kept in inclosures (*vivaria*) till the time appointed for the show. The exhibitor of the games (*editor spectaculorum*) presided on a seat (*pulvinar*) at the south side of the building. So passionately fond were the people of these games, that the expression *Panem et Circenses* ("Bread and the Circensian Games") was commonly used to signify the two prime necessities of life to the Roman populace. The crowds brought together by the games naturally attracted such persons as conjurers, jugglers, and fortune-tellers to the place, which is hence called by Horace (Sat. i. 6, 113), *fallax*, "deceitful." The splendour of the exhibition increased in the later times of the republic. P. Cornelius Scipio and P. Lentulus once exhibited 63 panthers and 40 bears and elephants (Livius, xlv. 18); and Pompey on one occasion is said to have exhibited 500 lions (a number beyond all belief), which were all despatched in five days. (Dion. Cass., xxxix. 38.)

CISSAMPELINE. [PELOSINE.]

CISS'AMPELOS PAREIRA, the Pareira-brava, a native of several

of the West Indian islands, of New Spain, and of Brazil. The root of this plant arrives in Europe in pieces from two to three feet long, varying in thickness from that of a finger to an arm, curved, furrowed, and warty, with a thin closely adhering bark of a grayish-brown colour. The woody part is tough, but so porous that air can be blown from one end to the other of a long piece; the concentric circles are very conspicuous; the axis is not in the centre. The odour is very faint, but the taste is at first sweetish or liquorice-like, afterwards nauseous and bitter. Analysed by Feneuille it was found to consist of—

Soft resin; a yellow bitter principle (tonic); a brown principle; animalised matter, starch, malate of lime, nitrate of potash, and other salts. Wiggers states that it contains a peculiar alkaloid, which he terms Cissampeline.

The juice of the fresh plant in its native country is said to be a very efficacious application to the bites of serpents; but in Europe the root is employed only as a tonic diuretic. It is particularly valuable in cases where there is a copious discharge of urine with aropy alkaline mucus. (Brodie's 'Lectures on Diseases of the Urinary Organs.') It is also serviceable in catarrhus vesicæ, and other affections of the urino-genital organs.

There is great reason to believe that the roots of several different species of this or closely allied genera are confounded under the name of Pareira-brava, especially the root of *Cissampelos Caapeba*, also of *C. Mauritanica* (Aubl.), *C. parviorides* (Decand.), which is much esteemed in the East Indies, given along with aromatics in diseases of the intestines. Two species of Aleuta, *A. rufescens* (Aub.) and *A. candicans* (Decand.), are used in Guiana.

The Pareira-brava contains so much mucilage that it coagulates water in which it is put to infuse. A syrup of this plant is a valuable demulcent in phthisis pulmonalis, or consumption.

CISSOID (*κισσοειδής*, resembling ivy), a name given to a curve first considered by Diocles (an Alexandrine, and posterior to Pappus, as is supposed from the latter not mentioning the name of Diocles among those who invented methods for inserting two mean proportionals 'Math. Coll.' book iii. prop. 5), which rises towards an asymptote, and then obtained its fanciful name. It was one of the curves employed by the Greeks in the celebrated problem of finding two mean proportionals, and is described as follows: Let two points (A) and (B) move with equal velocities round a circle, setting out from the ends of a diameter in opposite directions of rotation. Let a straight line (P) always pass through the starting point of (A), and through (B) as it moves; and let an ordinate (Q) perpendicular to the line joining the two starting points always pass through (A) as it moves. Then the intersection of (P) and (Q) traces out the cissoid, which has the line joining the starting points for its tangent at the commencement, and the tangent to the circle passing through the starting point of (B) for its asymptote.

But the term cissoid has been applied in later times to all curves described in a similar manner, and where the generating curve is not a circle. The cissoid of the Greeks should then be called either the cissoid of Diocles or the circular cissoid. The starting point of (A) being the origin, the line joining the starting points the axis of x , and a the radius of the circle, the equation of the cissoid of Diocles is—

$$y^2 = x^3 \div (2a - x)$$

CISTERCIANS. [BERNARDINES; CITEAUX.]

CITADEL (remotely from the Latin *civitas*, and immediately from the Italian *cittadillo*), a fortified post within or adjoining a town. It serves either to keep the inhabitants in subjection, or as a place of retreat for the garrison when compelled to abandon the town to an enemy. A citadel should be constructed in a situation where it may be easily succoured; its fortifications should be stronger than those of the town, in order that the enemy may be induced to attack the latter first; and it should be separated from the buildings of the town by an esplanade.

CITATION, a process in the commencement of a suit by which a party is commanded to appear before the Ecclesiastical courts. The jurisdiction of these tribunals in testamentary and matrimonial causes has been transferred to the Courts of Probate and of Divorce; and the first process in a suit in either of these courts is a *citation*. This is not, however, in the form of the abolished process, from which its name is derived, but rather resembles the writs in use in the Courts of Common Law.

CITEAUX, or, as it was formerly written, CISTEAUX (in Latin, CISTERCIUM), the site of a celebrated abbey in the department of Côte d'Or, in France: it is about four miles east from the town of Nuits, which lies on the road from Dijon to Châlons sur Saône. This abbey owed its origin to Robert, prior of Moutier-le-Celle, who, after endeavouring in vain to reform the irregularities of his convent, was solicited to take the charge of a company of anchorites, with whom he founded the abbey of Molême, and instituted a stern ascetic discipline. But becoming unable to maintain a strict conformity to his rules, he obtained permission of the papal legate to withdraw with a few chosen associates in order to following the Benedictine rule in its severest form. Accompanied by twenty followers, he retired to the forest of Cîteaux in 1098. After a time, Robert was directed by the pope to return to his charge at Molême, where the disorders which had probably caused his retirement had proceeded to a great length, in which office he continued till his death in 1108. The third abbot of Cîteaux was Etienne or Stephen Harding, an Englishman (canonised as St. Etienne), who may be regarded as the real founder of the Cistercian order (les Cîteaux), as until his time no establishment had sprung from this monastery: in 1113-15 were founded the first four establishments of which this can be regarded as the parent.

The monks of this order have been sometimes called Bernardines, from St. Bernard, who joined Etienne in 1113; and sometimes White Monks, from their habit, a white cassock with a white gown for attending the church, but a black one when they went abroad. The abbey of Cîteaux was a very rich establishment previous to the Revolution. The community consisted usually of about 80 monks, beside 40 domestics. The church and a chapel under the portico contained the tombs of about 60 princes of the ducal house of Burgogne, who made this their chief burial-place. Among those who have been inmates of this house, are St. Bernard and the four popes, Eugenius III., Gregory VIII., Celestine IV., and Benedict XII. The church and monastery have been destroyed, and there are now but few remains. Stephen, also, instituted the first female convent of the Benedictine order, which was succeeded by many others, but that of Port Royal has been by far the most distinguished.

CITHARA, an ancient stringed instrument of the lyre kind. That the names of the comparatively modern instruments, the gittern, or cittern, and guitar, are derived from the name of the Greek instrument (*κιθάρα*), we can have no doubt; and it is reasonable to infer, not only from similarity of appellation, but from the remains of antique art, that the modern instruments in many respects resemble that of the ancients. [LYRE.]

CITIZEN, from the French word *citoyen*, which remotely comes from the Latin *civis*. Aristotle commences the third book of his 'Politik' with an investigation of the question, What is a citizen (*πολίτης*)? He defines him to be one who participates in the judicial and legislative power in a state; but he observes that his definition strictly applies only to a democratical form of government. The Roman word *Civis*, in its original and proper sense, also meant one who had some share in the sovereign power in the state. The word citizen then, if we take it in its historical sense, cannot apply to those who are the subjects of an absolute monarch, or, in other words, of one who has the complete sovereign power. It is consistent with ancient usage and modern usage, and it is also convenient to apply the word citizen only to the members of republican governments, which term, as here understood, comprehends [REPUBLIC] constitutional monarchies. The term constitutional monarchy is not exact, but its meaning is understood: it is a form of republican government at the head of which is a king, or person with some equivalent title, whose power and dignity are hereditary. Constitutional monarchies approach near to absolute monarchies when the constitution gives very little power to the people, and this little power is rendered ineffectual by the contrivance of the prince and his advisers. Constitutional monarchies are of an aristocratical character when much political power is vested in the hands of a minority which is small when compared with the majority; or they may approach to a democracy, and differ from it mainly in having an hereditary instead of an elective head. Citizenship therefore is here understood as only applying to those states in which the constitution, whether written or unwritten, gives to those who are members of such states, or to some considerable number of them, some share of the sovereign power.

The usual form in which citizenship is acquired is by birth; by being born of citizens. In the old Greek states, and generally in those states of antiquity where citizenship existed, this was the only mode in which as a general rule it could be acquired. A person, not the son of a citizen, obtained no rights of citizenship by the mere circumstance of being born in a country or living there. Citizenship could only be conferred by a public act either on an individual or on all the members of other communities. Difference of religion was one of the causes of these communities excluding strangers from their political body. The Roman system was at first a close community, but the practice of admitting aliens (*peregrini*) to the citizenship was early introduced. They were even admitted by the old burgers (the patricians) in considerable numbers, but only by a vote of the collective body of patricians. The admission of aliens to the citizenship, either partial or complete, became a regular part of the Roman polity to which Rome owed the extension of her name, her language, and her power. It is true that the process of admission went on slowly, and for a long time the Romans unwisely, and with danger to their state, resisted the claims of their Italian allies, or subject people, who demanded the Roman citizenship; but this claim was finally settled in favour of the Italians by the Social or Marsic War (B.C. 90), and by the concessions that followed that war. The consequences of this war were, that all the inhabitants of Italy south of the Po became Roman citizens, and forty years afterwards the privilege was extended to the inhabitants north of the Po. We find some instances, before the Marsic war, of the states of Italy declining admission into the Roman political body; they preferred their own constitution to the rights and duties of Roman citizens. Under Justinian all free persons within the empire were *Cives*; but citizens had then become subjects, for the emperor was monarch.

The Roman system did not allow a man to claim the citizenship by birth, unless he was born of such a marriage as the state recognised to be a legal marriage. If a Roman married a woman who belonged to a people with whom the Roman state recognised no intermarriage (*conubium*), the child was not a Roman citizen; for he was not the legal child of his father, and it was only as the child of a Roman father that he could claim Roman citizenship. This was the strict principle; but it appears that if a Roman woman had a child by a man with whom there was no *conubium*, the child was legally a Roman citizen.

The English law gives the citizenship to all persons who are born anywhere of a British citizen or of one whose father or father's father was a citizen of Great Britain. The English law also gives the citizenship to every person born in the British dominions; which rule originated in the king claiming such persons as his subjects who were born within his dominions. In the earliest periods of English history, those were properly called subjects who may now properly be designated citizens, though citizenship in England must be divided into two kinds, as it was in Rome. Some native citizens do not enjoy the suffrage, nor are they eligible to certain offices, such for instance as a membership of the House of Commons. But these are not permanent and personal disabilities: they are temporary incapacities arising from not having a certain amount of property, and therefore the complete

citizenship may be acquired by every citizen who can acquire the requisite property qualification, with one or two trifling exceptions, such as a Jew or a Roman Catholic being disqualified from becoming Lord Chancellor. It follows from what has been said that those who happen to be under this disability are not full citizens, but have a capacity to become such. Those who have not the suffrage are in the situation of subjects to that sovereign body, of which those who possess the suffrage form a part. Thus the word subject may apply to some persons who live in a republic, as it does apply to all who live under a monarchy. The terms on which foreigners are admitted to the citizenship, are different in different countries. By the Act of Parliament 7 & 8 Vict. c. 76, the acquisition of partial citizenship in England is rendered much easier and less expensive than it was under the former process of a special Act of Parliament. [ALIEN.]

In ancient Rome, aliens were not always admitted to the full rights of Roman citizens; and indeed in the early history of the state, even the plebeians formed a body who were without many of the privileges which the patricians enjoyed. A person might receive the Roman citizenship so far as to enjoy every advantage except a vote at the public elections and access to the honours of the state. This however was not citizenship as understood by Aristotle, nor is it citizenship as understood by the free states of modern times. The acquisition of complete citizenship implies the acquisition of a share of the sovereign power: the acquisition of all the rights of a citizen, except the suffrage and access to the honours of the state, is a limited citizenship; and it is no more than may be acquired in those states where there is no representative body, and in which a man by such acquisition gets not citizenship, but the state gets a subject.

The great facilities for a man changing his residence which now exist, and the increased motives to such change in a desire to better his condition by permanently settling in another country, lead to emigration from one country to another, and more particularly from Europe to America. The advantage which any country receives from the emigration of those who possess capital or peculiar arts is so great that, under the present circumstances of the world, it is not easy to discover any good reason for republican governments refusing to give the citizenship to any person who comes to another country with the view of settling there. A difficulty will arise in case of war when a man owes a divided allegiance, for it is a principle of English law that a man cannot divest himself of his allegiance to the king of England; and probably an American citizen cannot divest himself of his allegiance to the United States. And yet the two countries which maintain this principle, allow the citizens of any other country to become citizens of their several communities. The Roman principle under the Republic was, that as soon as a Roman was admitted a citizen of another state, he ceased to be a Roman citizen, because a man could not belong to two states at once; wherein we have one among many examples of the precision of Roman political principles. The same principle must certainly be adopted some time into the international law of modern states.

The nations of Europe and the states of the two Americas have all a common religion, which however contains a great number of sects. A person of any religion in the United States of North America may become a citizen, and his opinions are no obstacle to his enjoying any of the honours of the country. But this was not so in England till 1858. No man for instance, though an English citizen, could be a member of the House of Commons unless he was, or was willing to profess that he was, a Christian. The declaration made by members of the House of Commons, which contained the words "upon the true faith of a Christian," excluded all who did not profess Christianity. In 1858, after several Jews had been elected members and had been prevented from sitting, an Act was passed, by which the House of Commons is enabled, by resolution, to exempt any member from repeating that part of the declaration.

A great number of foreigners, particularly from Great Britain and Ireland, and from some of the German states, annually settle in the United States of North America; and it is now alleged that by their numbers they materially affect the elections. It is also alleged that many of them are very ignorant, and for want of previous education and proper habits are incompetent to exercise the functions of an American citizen. It is further alleged that a great many of them are Roman Catholics, who are under a sort of obedience to a foreign prince, the Pope of Rome, and hostile to the principles of the American constitution. For these and other like reasons it has been proposed that a longer term of probation than five years should be required of aliens before they are admitted to the franchise; and a party which calls itself the American Republican party would make the period of probation twenty-one years. It is admitted in the argument of their party that if foreigners on settling in the United States are not allowed to have the franchise during the period of probation, they are during that period subjects to the citizens of the United States and not American citizens; which is consistent with what Aristotle says ('Pol.' iii. 1). If the period of probation is extended to twenty-one years, the citizens of the United States will have among them a great number of subjects—a great number of persons who will be as much their subjects as the people of Prussia are the subjects of the king of Prussia. The period of twenty-one years will comprehend the whole life of the great body of immigrants, and this body will be

very numerous. The immigrants will enjoy no more privileges than aliens can enjoy in most countries of Europe, but they will have before their eyes the daily spectacle of a large number of citizens who do enjoy rights which they do not. Whether all these circumstances will render the government of so large a body of subjects an easier thing to deal with than the difficulties that are alleged to grow out of the present terms on which the citizenship is given, remains to be seen. The declared hostility of the American Republican party to the Roman Catholic religion, the religion of a great number of the immigrants, is calculated to embitter these immigrants still more if they are deprived of the power of attaining the citizenship. The United States already possess a great number of slaves who are subjects, and a large body of free coloured people who are looked upon as a different caste. To these a party now proposes to add a large body of alien subjects, to add to the elements of discord one element more; and that a more powerful element than all the rest. Undoubtedly, the great amount of immigration into the United States is not a pure advantage to that country, but the call for different terms of naturalisation seems to proceed more from party and religious feeling than to be founded on sober reflection. If we consider the measures proposed, the reasons given for them, and the temper with which they are urged, we must agree with the party which urges them, that the American nation has rapidly grown up "without political experience adequate to govern their own mighty physical power."

In a narrower sense the term citizen is used to denote the freeman or elector of the corporation of a city, as distinguished from a burgher, the elector of a borough.

CITOLE, a musical instrument mentioned in the 'Confessio Amantis' of Gower, which was, Sir John Hawkins conjectures, a dulcimer.

CITRACARTIC ACID. [CITRIC ACID, *Mesaconic Acid*.]

CITRACONAMIC ACID ($C_{10}H_7NO_6$). An acid obtained as an ammoniacal salt, by boiling *citraconimide* with ammonia. Its salts are uncrystallisable.

CITRACONANILE. [CITRIC GROUP.]

CITRACONANILIC ACID. [CITRIC GROUP.]

CITRACONIMIDE. [CITRIC GROUP.]

CITRACONIODANILE. [CITRIC GROUP.]

CITRAMIDE. [CITRIC ACID.]

CITRANILIC ACID. [CITRIC ACID.]

CITRANILIDE. [CITRIC ACID.]

CITRATES. [CITRIC ACID.]

CITREN ($C_{10}H_8$). The volatile oil of lemons consists almost entirely of a peculiar carburetted hydrogen, to which the name of citren has been given. It is sometimes called citronyl.

CITRIBIC ACID. [CITRIC ACID.]

CITRIC ACID ($C_{12}H_8O_{14}$). This acid, discovered in 1784 by Scheele, in orange juice, exists in the free state, or as acid salt, in the juice of several fruits, as lemons, oranges, cherries, strawberries, red currants, &c., and in the berries of several vegetables; and to its presence the agreeable acidity of these fruits is due. It is usually prepared from lime-juice, which for this purpose is largely imported from Sicily. In order to obtain the acid, the lime-juice is allowed to stand until it undergoes incipient fermentation, by which certain mucilaginous matters are got rid of, and a clear liquor is obtained. This is neutralised, at first with chalk, and afterwards with caustic lime. An insoluble citrate of lime is hereby formed, which is washed with water, and then decomposed by the addition of a slight excess of dilute sulphuric acid. The liquid filtered from the sulphate of lime, and evaporated, yields crystals on cooling. The slight excess of acid promotes the crystallisation.

The acid is present in large quantities in gooseberries, from the expressed juice of which it may be obtained by the above process. The berries should be collected before they are ripe.

Citric acid crystallises in rhomboidal prisms, which have a strong and agreeable acid taste. It is soluble in alcohol, and more so in water. It is almost insoluble in ether. The crystals obtained by the spontaneous evaporation of a cold saturated solution, have the formula $C_{12}H_8O_{14} \cdot 3HO + 2HO$; those deposited by the cooling of a hot solution have the composition $C_{12}H_8O_{14} \cdot 3HO + HO$. A dilute aqueous solution becomes mouldy on standing.

It does not precipitate potash salts, and the presence of tartaric acid, with which it is frequently adulterated, may be detected by adding to a solution of the acid a little acetate of potash; the formation of a precipitate indicates the presence of tartaric acid. When solution of citric acid is added to lime-water, the liquid remains transparent, but on being heated deposits citrate of lime. This deportment serves to distinguish it from tartaric acid.

Heated with hydrate of potash, at a temperature of 392° Fahr., it is decomposed, with formation of acetate and oxalate of potash:—

Dry citric acid is decomposed, by treating with strong sulphuric acid,

into carbonic oxide, carbonic acid, and other products. By sulphuric acid and bichromate of potash it is oxidised into formic acid and carbonic acid. Dilute nitric acid does not attack citric acid in the cold; at a high temperature it oxidises it, with the formation of oxalic, acetic, and carbonic acids. A concentrated aqueous solution absorbs chlorine very rapidly when exposed to the sunlight: a yellowish oil is obtained, of a sweet but burning taste, and an irritating odour. Agitated with water, and cooled, the oil solidifies to a mass of crystals. The action of chlorine on citrate of soda produces different results,—an oil of complex composition is obtained, containing chloroform. Bromine gives similar results.

When crystallised citric acid is subjected to destructive distillation, it first melts, gives off its water of crystallisation, and at about 350° Fahr. it undergoes decomposition; gases and inflammable vapours are formed, and the residue no longer consists of citric acid, but is *aconitic acid*, called also *quisetic* or *atridic acid* ($C_{12}H_5O_9, 3HO$). If the heat be still increased, dense vapours appear, which condense to oily drops, and afterwards solidify to a crystalline mass of *itaconic acid* ($C_{10}H_4O_6, 2HO$); and if these crystals be repeatedly distilled, an oily mass of *anhydrous citraconic acid* ($C_{10}H_4O_6$), called also *pyrocitric* and *citribic acid*, is obtained, which does not solidify.

Citric acid is extensively used as a mordant in calico-printing. It is used in pharmacy for the preparation of syrups and lemonade. Mixed in small proportion with sugar and aromatic substances, it serves to form dry lemonade.

The crystallised acid loses two equivalents of water when heated below 212°. Its composition then is $C_{12}H_5O_{14} = C_{12}H_5O_{11}, 3HO$.

Citric acid is a tribasic acid, and is capable of forming three series of salts. It contains the tribasic radical *citryl*, $C_{12}H_5O_8$, which, when united with three equivalents of oxygen, forms the anhydrous acid, $C_{12}H_5O_{11}$; and united with three equivalents of chlorine, forms the chloride of *citryl*, $C_{12}H_5O_8, Cl_3$.

The composition of the citrates may be thus written:—

Neutral	trimetallic citrates	$C_{12}H_5O_{11}, 3MO$
Acid	bimetallic citrates	$C_{12}H_5O_{11}, (2MO + HO)$
Acid	monometallic citrates	$C_{12}H_5O_{11}, (MO + 2HO)$

Citric acid also forms polybasic salts; with lead this is more especially the case. Their general formula may be written—

The alkaline citrates are very soluble in water, and crystallisable with more or less facility. Like the tartrates, they prevent the precipitation of the salts of iron, manganese, &c., by alkalies. The citrates of magnesia, zinc, iron, cobalt, nickel are soluble. The neutral citrates of baryta, strontia, lime, on the other hand, are very little soluble; the acid salts more so. The citrate, and ammonio-citrate of iron, are frequently used in medicine. Their exact composition is not known.

Citric ethers.—The ethers of citric acid correspond to citrates in which the metal is replaced by its equivalent of methyl, ethyl, or amyl. The acid ethers form salts with bases:—

Methylocitric ether	$C_{14}H_{10}O_{14} = C_{12}H_5O_{11}, C_2H_5O \left. \begin{array}{l} 2HO \\ \end{array} \right\}$
Bimethylocitric ether	$C_{16}H_{12}O_{14} = C_{12}H_5O_{11}, 2C_2H_5O \left. \begin{array}{l} HO \\ \end{array} \right\}$
Neutral citrate of methyl	$C_{18}H_{14}O_{14} = C_{12}H_5O_{11}, 3C_2H_5O$
Neutral citrate of ethyl	$C_{24}H_{20}O_{14} = C_{12}H_5O_{11}, 3C_4H_5O$

Citric ether, or neutral citrate of ethyl, is best prepared by saturating an alcoholic solution of citric acid with hydrochloric acid. The free acid is neutralised with carbonate of soda, and the residue treated with ether. On the evaporation of the ether, the citrate of ethyl is left as a yellowish, transparent, heavy oil, which cannot be distilled without decomposition.

Amylocitric acid $C_{22}H_{18}O_{14} = C_{12}H_5O_{11}, C_{10}H_{11}O \left. \begin{array}{l} 2HO \\ \end{array} \right\}$ obtained by digesting citric acid with amylic alcohol, is a viscous liquid presenting traces of crystallisation. It forms crystallisable salts with alkalies. *Acid citrate of ethyl and amyl* $C_{26}H_{22}O_{14} = C_{12}H_5O_{11}, C_{10}H_{11}O \left. \begin{array}{l} C_4H_5O \\ HO \end{array} \right\}$ is obtained by saturating an alcoholic solution of the preceding compound with hydrochloric acid.

Amides and anilides of citric acid. The only amide of citric acid known is *citramide* ($C_{12}H_{11}N_3O_8$), prepared by the action of ammonia on citric ether. It represents neutral citrate of ammonia, minus six equivalents of water.

Citramide may be regarded as being 3 eq. of ammonia, in which the tribasic radical *citryl* ($C_{12}H_5O_8$) replaces 3 eq. of hydrogen $C_{12}H_5O_8''' \left. \begin{array}{l} H_3 \\ H_3 \end{array} \right\} N_3$.

Being a tribasic acid, citric acid ought to form amide compounds, corresponding to each of its ammonia salts. These have not been obtained, but Pebal has investigated the corresponding anilide compounds. They are formed by the action of aniline on citric acid, under varying conditions. They are of complex constitution and great

theoretical interest. For a full account the reader is referred to the original papers in Liebig's 'Annalen,' or Watts' English edition of Gmelin's 'Handbook of Chemistry.' A few only are enumerated here.

Citranilide, or *phenylcitramide* ($C_{48}N_3H_{23}O_8$), is tribasic citrate of aniline, minus 6 atoms water.

It may be considered to be derived from 3 atoms NH_3 , in which 3 atoms H are replaced by the radical citryl, and by 3 atoms of phenyl $C_{12}H_5O_8''' \left. \begin{array}{l} (C_{12}H_5)_3 \\ H_3 \end{array} \right\} N_3$.

Citrobianilide, or *phenylcitramide* ($C_{36}H_{16}N_2O_8$), a neutral body, formed from bibasic citrate of aniline by the loss of 6 atoms water.

It may be viewed as a diamide, that is, 2 eq. of ammonia, in which 3 atoms hydrogen are replaced by citryl, and 2 atoms by 2 of phenyl $C_{12}H_5O_8''' \left. \begin{array}{l} (C_{12}H_5)_2 \\ H \end{array} \right\} N_2$.

Citrobianilic acid ($C_{36}N_2H_{15}O_{10}$) is bibasic citrate of aniline — 4 atoms water. It forms crystalline salts.

Citranilic acid $C_{24}NH_{11}O_{10}$, obtained by the action of heat on monobasic citrate of aniline.

It may be derived from the type, hydrated oxide of ammonium $NH_4 \left. \begin{array}{l} H \\ \end{array} \right\} O_2$ in which 3 at. are replaced by citryl, and 1 at. H by phenyl, $N, C_{12}H_5, C_{12}H_5O_8''' \left. \begin{array}{l} H \\ \end{array} \right\} O_2$. It forms crystalline salts.

Chloride of citryl ($C_{12}H_5O_8Cl_3$). When citric acid is treated with pentachloride of phosphorus it becomes heated, and yields a mixture of oxychloride of phosphorus and *oxychlorocitric acid*, $C_{12}H_5O_{12}Cl_2$, a body crystallising in long silky needles, and which, with water, regenerates citric acid and hydrochloric acid. The mixture further heated, gives off hydrochloric acid and *chloride of citryl*, $C_{12}H_5O_8Cl_3$, appears to be formed.

Acids derived from citric acid by the action of heat.

Aconitic acid, $C_{12}H_5O_{12} = C_{12}H_5O_9, 3HO$. This acid is found as lime salt in many species of *aconite*. It is also found in *quisetum*, and was termed *quisetic acid*. It is formed from citric acid by heat, and this is its best source. Citric acid is distilled until crystalline striæ appear in the receiver. The residue dissolved in alcohol, and saturated with hydrochloric acid, forms aconitic ether, which treated by potash yields aconitate of potash. This is precipitated by a soluble lead salt, and the aconitate of lead formed decomposed by sulphuretted hydrogen, and the filtrate from the sulphide of lead evaporated.

It forms indistinct crystals, very soluble in alcohol and ether. It is formed from citric acid by simple loss of water.

Aconitic acid when heated assumes an amber colour, melts and boils at 320° Fahr. It then decomposes into carbonic acid, and a new acid, *itaconic acid*, which may be condensed in the receiver.

By this decomposition aconitic acid is distinguished from its isomers, fumaric and maleic acids.

Aconitate of lime, placed in contact with decaying cheese, is changed into succinic acid. Like citric acid, it forms three series of salts—monometallic, $C_{12}H_5O_9, (MO + 2HO)$; bimetallic, $C_{12}H_5O_9, (2MO + HO)$; and trimetallic, $C_{12}H_5O_9, 3MO$. They are little known, and are of no great interest.

Aconitic ether ($C_{12}H_5O_9, 3C_4H_5O$), obtained as above in the preparation of aconitic acid, is a colourless aromatic liquid, with a very bitter taste. It is rather heavier than water and boils at 425° Fahr.

By the action of aniline on aconitic acid compounds are obtained analogous to those derived from citric acid.

Pyrocitric acids. Under this name Gerhardt classes three isomeric acids derived from citric acid. They are itaconic, citraconic, and mesaconic acids.

Itaconic acid ($C_{10}H_6O_8$) occurs among the distillation products of citric acid, and is derived from the decomposition of aconitic acid. Citric acid is heated in a retort by means of a spirit lamp, until yellowish vapours, and an oily liquid passes over, which solidifies to crystals—these are pressed and recrystallised from water. Its crystalline form is a rhombo-hedral octohedron. It is inodorous, and has a strongly acid taste. Tolerably soluble in cold, and much more so in hot water. By heat it decomposes into anhydrous citraconic acid, and water.

It is bibasic, and forms two series of salts: $C_{10}H_4O_6(MO + HO)$ and $C_{10}H_4O_6 \cdot 2MO$.

Citraconic Acid ($C_{10}H_6O_8 = C_{10}H_4O_6 \cdot 2HO$). In the later stage of the distillation of citric acid an oily liquid passes over, which is *anhydrous citraconic acid* ($C_{10}H_4O_6$). When exposed to the air it attracts moisture, and becomes slowly converted into a crystalline mass of citraconic acid ($C_{10}H_6O_8$). Citraconic acid is isomeric with itaconic acid, but differs from that substance in its crystalline form, which is a four-sided prism, and also in being more soluble in water. Small quantities heated for some time to 212° are converted into itaconic acid. Citraconic acid is bibasic, like itaconic acid, and forms two series of salts.

Mesaconic acid, Citracartic acid ($C_{10}H_6O_8$). When a weak solution of citraconic acid is digested for some time with about $\frac{1}{10}$ th its volume of nitric acid, the liquid deposits after some time crystalline masses, of an aspect like porcelain, which when purified have the form of somewhat brilliant needles, which sublime without alteration, and are very slightly soluble in water, consist of mesaconic acid, and are produced by a simple isomeric transformation of citraconic acid. Itaconic acid, when acted upon by nitric acid, does not yield mesaconic acid. Mesaconic acid is bibasic, and forms two series of well defined salts.

The neutral ethers of these three isomeric acids, *itaconate*, *citraconate*, and *mesaconate of ethyl*, are also isomeric, and their formula is $C_{10}H_4O_6 \cdot 2C_2H_5O$. They are all produced by dissolving the acid in alcohol, and etherifying by means of hydrochloric acid. The two former are oily aromatic liquids with a bitter taste, slightly heavier than water. They boil at 437° Fahr. under partial decomposition. Mesaconic ether has a pleasant fruity odour, it boils at 428° Fahr., and distils without alteration.

Brominated derivatives of the pyrocitric acids. By the action of bromine on either neutral citraconate or itaconate of potash in the presence of water, carbonic acid is evolved, and a yellow oil deposited which is a mixture of two substances. The one is a heavy, neutral, amber-coloured fluid; its formula is $C_6H_3Br_3O_2$ which is that of a terbrominated acetone or terbrominated propionic aldehyde. The other substance is *bromotricarboxylic acid*, and can be separated from the mixture by potash. Frequently, after standing, the oil solidifies to a mass of crystals. It forms salts. Its formula is $C_6H_3Br_3O_4$ which is that of a bibrominated butyric acid; but its discoverer, M. Cahours, was not able to prepare it from butyric acid.

If bromine act on citraconate or itaconate of potash in the presence of excess of potash, the reaction appears to take place in an analogous manner, but the resultant product is an acid, *bromitonic acid* ($C_6H_3Br_3O_4$), or a bibrominated propionic acid.

Chloride of pyrocitryl ($C_{10}H_4O_4Cl_2$). This substance is produced by the action of pentachloride of phosphorus on anhydrous citraconic acid. It is a fuming, heavy, refringent liquid, which boils at 347° Fahr. It is decomposed by water into hydrochloric and citraconic acids.

The amides and anilides of the pyrocitric acids have been carefully investigated by Gottlieb, to whose papers in Liebig's 'Annalen,' vols. 77 and 85, the reader is referred for details.

CITRIC GROUP. A family of organic compounds belonging to the *acetic series*. It comprehends citric acid and its derivatives. The citric group is attached to the acetic series by several reactions: for instance, citric acid gives by destructive distillation *acetone*, and when heated with hydrate of potash it is converted into acetate and oxalate of potash. The following are amongst the principal members of this group:—

Citric acid		$C_{12}H_8O_{14}$
Citramide		$C_{12}H_{11}N_3O_8$
Aconitic acid		$C_{12}H_6O_{12}$
Pyrocitric acid		$C_{10}H_6O_8$
Pyrocitramide		$C_{10}H_8N_2O_4$
Pyrocitramic acid		$C_{10}H_7NO_6$
Pyrocitrimide		$C_{10}H_5NO_4$
Citric ether		$C_{12}H_5O_{11} \cdot 3C_2H_5O$
Citraconanile		$C_{10}H_4(C_{12}H_5)NO_4$
Citracondinitranile		$C_{10}H_4(C_{12}H_5(NO_2)_2)NO_4$
Citraconimide		$C_{10}H_5NO_4$
Citraconiodanide		$C_{10}H_4(C_{12}H_4I)NO_4$

For a detailed description of such of these bodies as are not mentioned under their respective names, see Gerhardt's 'Traité de Chimie,' vol. ii. p. 85.

CITROBIANILE. [CITRIC ACID.]

CITROBIANILIC ACID. [CITRIC ACID.]

CITRONYL. [CITREN.]

CITRUS AURANTIUM, ORANGE, of which there are two species, the sweet, or China orange, *Citrus Aurantium, Risso*, and *C. Bigaradia, Risso*, and the bitter, or Seville. The fruit of the latter, while small and unripe, is collected and dried: the smallest, which are of the size of a pea, are used for keeping issues open, and the larger for the preparation of the liqueur called Curaçoa. Of the ripe fruit every part is used either medicinally or dietetically. The rind, called flavedo, contains a bitter principle and much volatile oil; and either used at dessert, or reduced to powder and added to magnesia and rhubarb, furnishes a grateful tonic to the stomach in some forms of dyspepsia and gout. The pulp and juice are exceedingly agreeable to persons affected with inflammatory complaints, or a drink prepared from it (orangeade) is of great utility in bilious and gastric fevers, dysentery, &c. The roasted pulp forms an excellent application to fetid ulcers.

The peel of lemons is likewise employed, but it is not so warm and grateful as that of oranges, from containing less volatile oil. The powers of lemon juice are much increased by saturating it with chloride of sodium (common table-salt). It is then of great efficacy in the treatment of dysentery, remittent fever, the dry belly-ache, putrid sore throat, and other diseases occurring in the West Indies. Dr. Wright also recommends it in diabetes and lenteria. Similarly mixed with table-salt, but without sugar, it is one of the best drinks against sea-sickness.

Citric acid exists in numerous fruits, particularly those of the orange tribe, such as the lemon and lime, either alone, or with malic and other acids; sugar, mucilage, and extractive are also present. The citric acid is separated and purified on a large scale, in the way before mentioned. [CITRIC ACID.] It is frequently adulterated with other acids, such as tartaric, sulphuric, muriatic, and oxalic, which may be detected by appropriate tests. Citric acid, when crystallised, has scarcely any odour, but a very distinct acid taste. It is soluble in cold, but more abundantly in warm water. Citric acid has the power of curdling the milk of most animals, but not the human milk.

As it is impossible to treat of citric acid apart from lemon juice, we class them together. The impression of both on the organ of taste is the same in kind, but different in degree. Concentrated citric acid is somewhat caustic, but lemon juice is gratefully acid. To imitate the natural state, citric acid is only given largely diluted. In this state it proves a pleasant drink in fevers and diseases where the temperature of the body rises above the natural standard. According to Broussais, it agrees better than any other acid with the stomach when affected with acute inflammation. It is not so pleasant as lemonade prepared from new fresh lemons, and according to the statement of Sir G. Blane, the solution of citric acid is not so efficacious in the prevention and cure of sea-scurvy as the recent lemon juice. This is attributable to the absence of the volatile oil and the bitter principle of the rind, which are valuable adjuncts to the citric acid in its action on the stomach. The utility of lemon juice in promoting the digestion of gelatinous meats, such as veal and turtle, is well known. Fresh lemon juice may be preserved in bottles in the same way as ripe fruits, by boiling the bottles in which it is contained for half an hour, first placing them in cold water, and gradually heating it, and as soon as the contents of the bottles have fallen to the temperature of the air, closing them hermetically. Where lemon juice so preserved, or fresh lemons, cannot be obtained by ships on long voyages, the dissolved citric acid, to which a portion of an alcoholic extract of lemon peel may be added at the time of using, must serve as a substitute, should any apprehensions of scurvy be entertained. Its efficacy as a daily drink, without sugar, properly diluted, in improving the health of feeble children, is most striking.

Lemon juice is often a means of correcting acidity in the stomach, since, like most vegetable acids, it elevates the vitality of that organ, and prevents the formation of an excess of acid. On the same principle it is found to be a useful agent in elevating the powers of the stomach in the intermittent, remittent, and bilious fevers of America, many cases of which have yielded to a combination of lemon juice, cinchona bark, and port wine. Lemon-juice has been recommended on theoretical grounds, in acute rheumatism and gout, in large doses several times a day. Doubtless, its power in improving the condition of the digestive organs, may render it useful in some cases of these disorders. Lemon juice is often employed to rouse the stomach and nervous system after narcotic poisoning; but neither it nor vinegar should be used till all the poisonous substance is evacuated from the stomach, otherwise it increases the power of the poison.

Citric acid, as well as lemon juice, is much employed to decompose alkaline carbonates, forming therewith pleasant effervescing solutions. These taken in the act of effervescence are often of great utility in checking vomiting, and in reducing the temperature in inflammatory complaints. But in all cases of debility the employment of citric, or any other vegetable acid, for this purpose, is decidedly improper. The amount of injury done by the indiscriminate use of effervescing draughts made with a vegetable acid is incalculable. "Were I required," says Dr. Prout, "to name the medicine calculated to do the most mischief, I should name the common saline draught formed of potash or soda and some vegetable acid."

Citric acid alone is very useful in the phosphatic diathesis; it is the alkaline base in this combination which does harm. [CARBONIC ACID.]

Externally citric acid largely diluted has been beneficially employed as a refrigerating wash, in the same way as vinegar. Slices of lemon form useful applications to scorbutic and other sores, and also at the commencement of hospital gangrene.

CITRYL. [CITRIC ACID.]

CITTERN (or *gittern*, or *guiltern*), a musical instrument of the lute kind, mentioned by our old dramatists. [CITHARA.]

CITY. Certain large and ancient towns both in England and in other countries are called cities, and they are supposed to rank before other towns. On what the distinction is founded is not well ascertained. The word seems to be one of common parlance, or at most to be used in the letters and charters of sovereigns as a complimentary or honorary compellation, rather than as betokening the possession of any social privileges which may not, and in fact do not belong to other ancient and incorporated places which are still known only by the name of towns or boroughs.

Sir William Blackstone is unfortunate in his attempt to define it. "A city," he says, "is a town incorporated, which is or hath been the see of a bishop." ('Comm.,' *Introd.*, section iv.) But Westminster is a city, though it is not incorporated. Thetford is but a town, though incorporated, and once the seat of a bishop. Whether Westminster owes its designation to the circumstance that it had a bishop for a few years of the reign of Henry VIII., and in the reign of Edward VI., may be doubted. But there are, besides Thetford, many places which were once the seats of bishops, as Sherburn, and Dorchester in Oxfordshire, which are never called cities. On the whole we can rather say that certain of our ancient towns are called cities, and their inhabitants citizens, than show why this distinction prevails and what are the criteria by which they are distinguished from other towns. These ancient towns are those in which the cathedral of a bishop is found; to which are to be added Bath and Coventry, which, jointly with Wells and Lichfield, occur in the designation of the bishop in whose diocese they are situated; and Westminster, which in this respect stands alone. Manchester, after having become the seat of a bishop, was incorporated as a city; but Ripon, also made the seat of a bishopric, remains a borough.

CIVET. This substance, which possesses an odour analogous to musk, is obtained from two species of animals, namely, the *Viverra zibetha* and the *Viverra civetta*. By distillation civet yields an essential oil to which its odour is due.

CIVIC CROWN. Among the Romans the civic was considered more honourable than any other crown. It was the recompense for the life of a citizen saved, either in battle or assault. A civic crown was conferred on Cicero for detecting Catiline's conspiracy; and afterwards upon Augustus, the reverse of many of whose coins bears the representation of it, with the inscription OB CIVIS SERVATOS. This crown, which was in fact a wreath, was at first of elm, afterwards beech was used, and lastly, and most generally, oak. (Rasche's 'Lexicon Rei Numariæ.') Plutarch, in the life of Caius Marius Coriolanus, has given what he considers to be the reasons for the choice of the oak. Pliny informs us that the civic crown was the foundation of many privileges. He who had once obtained it had a right to wear it always. When he appeared at any of the public shows, the senators rose to do him honour; and he was placed near their bench. He was excused from all troublesome duties and services; and his crown procured the same immunity for his father and his grandfather on his own side. (The reader may consult for further information, Polyb. lib. vi. c. 37; Plin. 'Hist. Nat.' lib. xvi. c. 4; Tacitus, 'Ann.' lib. iii. § 21; xv. § 12.)

CIVIL LAW. This term is used in different senses. The Romans understood by the expression, "jus civile," the law, "quod quisque populus sibi constituit." In this sense, therefore, civil law might be defined to be the law of any particular nation or state. In place of this original and proper signification of the term, the expression "municipal law" has, however, very inappropriately been used by English writers; and civil law, in a more restrained sense, has now come to signify the law of the ancient Romans. [ROMAN LAW.] The term Civil law (the French *droit civil*, the German *Civil-Recht*) is still used, particularly in Germany and France, in another and limited sense, to denote the law given by the competent power of the state for regulating the mutual rights and obligations of the citizens or subjects as private persons; hence the expression "Civil Code" (*code civil*), and among the Germans, *civil*, or *bürgerliches Gesetzbuch*. [CODIFICATION.] German lawyers therefore say that civil law is a part of private law (*privat-recht*.) In this sense civil law is distinguished from other branches of law, as, for example, criminal law, ecclesiastical law, &c.

CIVIL LIST, as the words imply, was formerly the name given to the list of all the expenses of the civil government of the country, or of all the heads of public expenditure, excepting those of the army, the navy, and the other military departments. Originally in this country all the expenses of the government, the military expenses not excepted, were comprehended in one general list, and defrayed out of what was called the royal revenue. For a considerable period after the Conquest the royal revenue was derived from the rents of the crown lands, and from other sources which were at the command of the crown through the exercise of the prerogative. Both the collection and the expenditure of the whole were under the uncontrolled management of the king. Even when, at a later period, the greater portion of the expenses

of the government came to be granted by parliament in the form of supplies, the entire expenditure was still left with the crown, the supplies being either voted for no specific purpose, or when it was otherwise, no responsibility as to the application of them being enforced.

This state of things continued to the Restoration. A distinction was then made between the military expenses of the government, or those occasioned by the wars in which the country might be involved, and which were considered of the nature of extraordinary expenses, and those incurred in the maintenance of the ordinary establishments of the country. The revenues appropriated to the latter were called the hereditary or civil-list revenues, and were provided for partly from the crown lands that remained unalienated, and partly from certain taxes imposed by parliament expressly for that purpose during the life of the reigning king. The civil list thus obtained amounted, during the reign of William III., on an average of years, to the annual sum of about 680,000*l*. Out of this sum were paid the expenses of the royal household, of the privy purse, of the maintenance and repairs of the royal palaces, the salaries of the lord chancellor, of the judges, of the great officers of state, and of the ambassadors at foreign courts; the incomes of the members of the royal family, and many other pensions, the secret service money, and a long list of other claims. The interest of the national debt, however, was never defrayed from the sum allotted for the civil list. In succeeding reigns, while the amount of the civil list was increased, the appropriation remained much the same. On the accession of George III., the amount of the civil list, 800,000*l*., was voted by parliament, but no particular taxes were set apart to provide for it, and this practice has ever since continued. In 1780 Mr. Burke brought in his bill for the better regulation of the civil list, which, although it was greatly mutilated before it passed into a law (in 1782), abolished several useless offices, and effected some reduction of expenditure. Expenses, however, still continued to grow, and at length, in 1812, the annuities to various branches of the royal family, to the amount of 260,000*l*., were transferred to the consolidated fund. It was again raised, on the accession of George IV., by transferring charges to the same fund, to the amount of 255,000*l*. per annum. By the Act 1 Will. IV., c. 25, the civil list is confined to expenses proper for the maintenance of the royal household; and in the year ended June 30, 1859, the amount of the civil list, which is voted annually, was 402,835*l*. Her Majesty also retains the revenues of the duchy of Lancaster, which are considered to be the hereditary revenues, not of the crown, but of the dukedom of Lancaster, which is permanently annexed to the crown. The duchy of Cornwall belongs to the Prince of Wales. The charges which used to be defrayed from the civil list are now provided for separately, and in the same year mentioned above were as follow: annuities and pensions, 346,678*l*.; salaries and allowances, 158,624*l*.; diplomatic salaries and pensions, 163,066*l*.; courts of justice, 722,889*l*.; and miscellaneous charges, 175,738*l*.; making a total of 1,969,830*l*.

CLAIM IN CHANCERY. [EQUITY.]

CLAN, in Gaelic *Clann*, which is said to signify children or descendants. The word has been long adopted as English. Milton says,

"They around the flag
Of each his faction, in their several clans," &c.
Par. Lost, ii. 901.

The clans of the Highlands of Scotland are families, or rather tribes, all the members of which bear the same surname, and are supposed to be descended from a common ancestor, of whom the chief of the clan is the lineal representative. Camden, and indeed all other authorities, speak of the Lowlanders and Highlanders as two distinct peoples; and they were generally hostile to each other, though under the same sovereign. Fletcher of Saltoun, in 1698, says of them: "It were to be wished that the government would think fit to transplant that handful of people and their masters (who have always disturbed our peace) into the Low country, and people the Highlands from hence, rather than they should continue to be a perpetual occasion of mischief to us." "Being divided," says Camden, speaking of the Scotch Highlanders, "into families, which they call clans, what with plundering and murdering, they commit such barbarous outrages that their savage cruelty hath made the law necessary which enacts, that if one of any clan hath committed a trespass, the rest shall repair the damage, or whoever of them is taken shall suffer death." Some clans are divided into several branches, each of which has its particular surname. According to Colonel Stewart, in his 'Sketches of the Character, Manners, and Present State of the Highlanders of Scotland' (2 vols. 8vo, Edinb. 1822), this surname, peculiar to the branch, is called the *bun sloine*, that is, the genealogical surname, being derived from the Christian name or other designation of the ancestor of the branch. It is the name generally used in common conversation; but every Highlander in writing his signature, and also for the most part when he has to mention another person in writing, uses the name which is common to the whole clan. Most of the Highland noblemen and gentlemen have designations peculiar to them as chiefs of their clans, which in their own country no feudal titles or distinctions, however exalted, are allowed to efface. "Besides his ordinary name and surname," says Sir Walter Scott (note to 'Lady of the Lake,' canto ii.), "which were chiefly used in the intercourse with the Lowlands, every Highland chief had an epithet expressive of his patriarchal dignity as

head of the clan, and which was common to all his predecessors and successors, as Pharaoh to the kings of Egypt, or Arsaces to those of Parthia. This name was usually a patronymic, expressive of his descent from the founder of the family. Thus the Duke of Argyle is called Mac Callum More, or the *Son of Colin the Great*. Sometimes, however, it is derived from armorial distinctions, or the memory of some great feat: thus Lord Seaforth, as chief of the Mackenzies, or Clan-Kennet, bears the epithet of Caber-Fae, or *Buck's Head*, as representative of Colin Fitzgerald, founder of the family, who saved the Scottish king when endangered by a stag."

Although the chieftainship of the clan now descends regularly from father to son or other male heir, there can be little doubt that in ancient times the custom of tanistry prevailed among the Scottish Highlanders, as it did down to a comparatively recent date among the Irish. [BREHON LAWS.]

In Gaelic the individuals of a clan were distinguished from each other by the addition to their own name of that of their fathers; as, Roderick vich Alpin,—that is, son of Alpin; sometimes with the further addition of the name of the grandfather, and the patronymic of the clan was only used to or by strangers.

The common prefix of the Scottish patronymics of clans is *Mac*, that of the Irish *O'*—both signifying son, or at least descendant. But many Irish names also begin with *Mac*, and some with the synonymous Norman *Fitz*, the same word with the modern French *fils*; and the *vich*, or *wich*, used as an affix in the same sense by the Russians, is almost identical with the Gaelic. Several of the Scottish clans, however, have surnames in which the common prefix does not appear; as, for instance, the Stewarts, the Gordons, the Robertsons, the Camerons, the Campbells, the Chisholms; and the Clan Chattan, once a very powerful one, had for its head Mackintosh of Mackintosh, captain of Clan Chattan; while the offshoots, still claiming to belong to the clan, took the names of Macgillivray, Macbean, Macqueen, Macphail, Shaw, Gow or Smith, Davidson, Clark, and others. Several of these clans are generally understood not to be of Celtic descent; or rather, the chieftainship has passed by marriage or otherwise into Lowland, Norman, or Saxon families. Indeed, the tribes inhabiting the southern borders of Scotland, whose connection with, and dependence upon their chiefs used to be nearly as complete as that which prevailed in the Highlands (see the Introduction to Scott's 'Minstrelsy of the Scottish Border'), are often also familiarly spoken of as clans. Scott, in the battle canto of Marmion, says:

"Against them come,
Of gallant Gordons many a one,
And many a stubborn Badenoch man,
And many a rugged border clan,
With Huntley and with Home."

And the old Scottish statutes, passed in the 16th century for regulating the Borders, speak of "clans having captains and chieftains, on whom they depend, oft-times against the wills of their landlords." "Of course," says Scott, referring to Acts passed in 1574 and 1587, "these laws looked less to the feudal superior than to the chieftain of the name for the restraint of the disorderly tribes; and it is repeatedly enacted, that the head of the clan should be first called upon to deliver those of his sept who should commit any trespass, and that on his failure to do so he should be liable to the injured party in full redress." ('Introduction to Border Minstrelsy.') The essential distinction was, that in the Highland clans, the chief was the head of the family; the whole of the land was his, but only held for the benefit of the whole, which he apportioned as he thought proper; while every individual looked to the chief for maintenance and support. In the Lowlands, and on the Borders, the feudal system prevailed, and property was individualised under certain stipulations for services, civil or military. The difference was shown very remarkably after the rebellions of 1715 and 1745, when, though many of the territorial possessions were forfeited by the chiefs and transferred to other proprietors, the cultivators long continued to consider the old chiefs as the rightful owners, and paid them their tribute accordingly. Also, after the abolition of hereditary jurisdictions in 1748, the great Highland proprietors felt the support of their clans a heavy burden, of which they endeavoured to rid themselves. As the clansmen held no distinct portion of the land, the chief had only to reduce the number of his followers, and he increased the extent of his own possessions. To effect this, considerable severity was used in too many cases, and large numbers of families were evicted from holdings possessed by their ancestors for centuries, to make room for cattle and sheep.

According to Colonel Stewart ('Sketches,' &c., vol. i.), the Gaelic clans of Scotland occupied the counties of Sutherland, Caithness, Ross, Inverness, Cromarty, Nairn, Argyle, Bute, and the Hebrides, with part of Moray, Banff, Stirling, Perth, Dumbarton, Aberdeen, and Angus. He has given a map of Scotland, in which the locality of each clan is marked; and in the second and third sections of his work he describes and examines the system of clanship and its consequences. In his second volume, Appendix Q, is on the Distinctive Patronymics of the Clans. In Robert Patten's 'History of the Rebellion of 1715' (3rd edit., 8vo, Lond. 1745), pp. 191-199, is given 'A List of the most considerable Chiefs in Scotland, and the number of men they can raise, with an account of their disposition for or against the government,'

which includes the clans. 'Note,' says Patten, "that all the chiefs in Scotland are chiefs of clans, properly so speaking, whether noblemen or gentlemen; but commonly the last only are called the clans, and particularly those of them who live in the north and west Highlands and Isles." Patten's list may be compared with a 'Memorial on the Military strength of the Clans,' which Colonel Stewart has printed in his Appendix C, and which he conceives to have been drawn up a short time before the rebellion of 1745 by President Forbes. Bishop Nicholson has printed in his 'Scottish Historical Library,' from Bell's manuscript 'Introduction to the History of Cumberland,' a catalogue of the chiefs and clans of what was called the west border of the south of Scotland, that in 1547 submitted and gave pledges to Lord Wharton, who had overrun the country, that they would serve the King of England, with the number of followers they could command annexed to the name of each. It has been transferred by Scott to a note on his 'Introduction to the Border Minstrelsy,' along with a list of the east Border chiefs who did homage the same year to the Duke of Somerset, from William Patten's diary of the duke's expedition, originally printed in 1548, and reprinted in Dalrymple's 'Fragments of Scottish History.'

The system of clanship, as it subsisted in the Highlands of Scotland, making allowance for the modifications it received from feudalism, in respect of the tenure of property superinduced upon its original purely patriarchal character, is essentially the same state of society that has always prevailed among the wandering Arabs and Tatars of the East. Gibbon's description of the social condition of the Tatars, or, as he calls them, Scythian hordes, in his 26th chapter, would, in great part, suit the state of things in the Highlands, at least as it remained down to the rebellion of 1745. Since that attempt, the measures which the government was induced to take in consequence of it, and, in a still greater degree, the progress made in agricultural and commercial improvement in every part of the Highlands, has reduced the old spirit of clanship to a mere name.

CLARE, NUNS OF THE ORDER OF ST., were instituted by that person at Assisi, in Italy, according to Newcourt, about A.D. 1212. This order was confirmed by Pope Innocent III., and, after him, by Pope Honorius III., A.D. 1223, and was subsequently divided into a stricter and a looser sort. (Newc. 'Repert. Ecclesiast.' vol. i. p. 562.) "St. Clare," says Tanner, "was born in the same town and lived at the same time with St. Francis, and her nuns observing St. Francis's rule, and wearing the same coloured habit with the Franciscan friars, were often called Minorettes, and their house without Aldgate (London), the Minories." They were brought into England by Blanche, queen of Navarre, who was wife to Edmund earl of Lancaster, Leicester, and Derby, under a licence from King Edward I., A.D., 1293. Besides this, there were only three other houses of this order in England, viz. Waterbeche and Denny, in Cambridgeshire, and Brusyard in Suffolk.

CLARENCEUX, the name of one of the provincial kings-of-arms in the Herald's College. As early as the reign of Edward III. there were two kings-of-arms, who bore the titles of Surroy and Norroy (that is, South and North Kings). Lower ('Curiosities of Heraldry') states that the title of Surroy was changed to Clarenceux by Henry V., who, preferring the herald of his brother Thomas, Duke of Clarence, constable of the army, created him a king-of-arms, and placed the part of England south of the Trent under his care. William Horseley was so created by Henry V., and Roger Lygh by Henry VI. Afterwards it sunk into the office of a herald only, but was again revived in the reign of Edward IV. in favour of William Hawkeslow, who had, however, the west of England only allotted to him as a province. Sir Thomas Holme, knight, who succeeded to the office in 1476, appears to have had first the west, and then the south of England, as the district in which he was to give armorial bearings. This privilege is now exercised by Clarenceux and Norroy concurrently with Garter.

The arms of Clarenceux are, argent, St. George's Cross, upon a chief gules a lion of England crowned with an open crown. The badge is the same, in an escutcheon, crowned with a crown of a king-of-arms, upon a green ground on one side; and on the other, the royal arms crowned upon a white ground, pendent to a gold chain, or simple riband.

CLARENDON, THE CONSTITUTIONS OF, were certain resolutions, which were in effect ordinances agreed to at a general council of the nobility and prelates assembled by Henry II. at his palace or manor of Clarendon, in Wiltshire, in 1164. These enactments, which the preamble declares to be a record and recognition of the ancient laws and customs of the realm, were sixteen in number, and were intended to define the respective limits of the civil and ecclesiastical jurisdictions, to prevent further encroachments by the clergy, and to abolish the abuses which had arisen from the gradual and increasing usurpations of the pope. (Knight's 'Popular Hist. of England,' vol. i. p. 286.)

CLARET. [WINE.]

CLARIFICATION, as a manufacturing process, is a mode of clearing or cleansing liquids from certain impurities which affect the colour, odour, taste, or other qualities. According to the nature of the liquid, so does the clarifying agent vary. The process is often called "fining," in reference to the effect in rendering the liquid fine and bright. Some clarifiers act by combining with, or collecting the feculent matter, and subsiding with it to the bottom of the vessel. Others effect a chemical change in the floating impurities, and render them heavy enough to sink to the bottom by their own weight. The

list of clarifiers is considerable, including albumen, gelatine, blood, lime, plaster of Paris, alum, alcohol, sulphuric acid, sugar of lead, sulphate of potash, juices, marl, clay, &c. In clarifying syrups, albumen or white of egg is very useful; seeing that it combines with the impurities when cold, rises with them when heated, and then forms with them a scum which is easily removed. In clarifying the red wines and many kinds of liqueurs and cordials, white of egg is extensively used in a similar way. In clarifying white wines, beer, and cider, and several other beverages, isinglass is used instead of white of egg; the difference depending on certain differences in the chemical affinity of albumen and gelatine for the impurities in the two groups of liquids. To give the "sparkling" effect to liquids in the glass, so much vaunted by the keepers of gin-palaces, salts of lead and of potash are used in a mode not altogether free from poisonous tendencies. In clarifying cider and perry, clay and marl are often used. Coffee is often cleared by isinglass. Heat acts as a clarifier of certain liquids by curdling or coagulating the impurities, rendering them specifically heavier than before, and causing them to sink; and the same effect is produced in a modified way by the action of lime, alum, alcohol, and some of the acids. Bullock's blood is a very useful clarifier, because it is cheap, and because it will act as a substitute both for isinglass and for white of egg. Various modes of clarification will be found noticed under BREWING, CIDER, SUGAR, WINE, &c.

CLARINET, a musical instrument made of wood, similar in shape to the oboë, but of rather larger dimensions, and having a fixed mouth-piece containing a reed, which forms the upper joint of the instrument. It was invented at the commencement of the last century by Denner of Nuremberg, although many years elapsed before it came into general use. The clarinet gives all the sounds of the diatonic-chromatic scale, but the same instrument cannot be used in all the modes, or keys; hence in the orchestra three instruments are employed, of different dimensions, namely, a C, a B, and an A clarinet: that of B is preferred by performers, because it is more mellow in tone, and more manageable as regards fingering. The compass of the clarinet is from E, the third space in the base, to G in altissimo.

But in the orchestra it is seldom required to go higher than C# in alt.

The sounds between the lowest note (E) and B, the third treble line, are called *Chalumeau* notes, or notes resembling an ancient rustic instrument so named, which was formed of reed.

BASE CLARINET. This was invented, in 1828, by Streitwolf, an instrument-maker of Göttingen. It is made of wood, and played on in the same manner as the common clarinet. Its compass is four octaves, and it descends to B below the base staff. In length it is two feet eight inches.

CONTRA-BASE CLARINET. The same artist subsequently produced a *double-base* clarinet, which stands in the same relation to wind instruments of wood that the *contra-basso* (double-base) does to stringed instruments, and promises to become very useful in the orchestra. Its form and manner of fingering differ but little from those of the base clarinet: in size it is not larger than the bassoon, and in compass is four notes lower.

In the Great Exhibition of 1851, M. Boehm's instruments attracted attention, and are thus referred to in the Jury Report: "First, he has brought the acoustical proportions of tubes, and the finger holes of wind instruments into correct numbers and measurement, by which means flutes, oboës, clarionets, bassoons, &c., can be theoretically constructed. Secondly, he has invented a mechanism for the keys which gives facility and precision to the execution, and by which the former difficulty of reaching or stopping the holes at great distances, or of large sizes, is now surmounted. As by these means the holes can be made correct in size and position, M. Boehm has acquired not only a perfection in tone and tuning never before attained, but also a great facility in playing in those keys which were hitherto difficult, and defective in sonorousness or intonation."

CLARION, a kind of trumpet, very shrill, and not now in use.

CLAVICHORD (or, improperly, *clarichord*), a musical keyed instrument, much in use up to the middle of the last century, but now only to be met with as a curiosity. Its shape is that of a square pianoforte, though smaller, and the strings are struck, or rather pressed, by brass pins projecting from the further end of the keys. The tones of the Clavichord are rendered exceedingly soft by means of pieces of cloth interwoven with the strings. This softness was its great recommendation in convents, the nuns having thereby been enabled to practise without disturbing others in the dormitory.

CLAY (in Agriculture) is an essential component part of all fertile soils. A soil is clayey in proportion to the alumina [ALUMINA] united to silica of various degrees of fineness which it contains; these are also often united to a portion of carbonate of lime. When the silica is very fine and intimately mixed with alumina, the clay, although stiff

in appearance, is fertile in proportion to the humus which it contains, or which is artificially added to it. It then forms that class of rich wheat soils which produce many successive abundant crops without change or manure. It has a strong affinity for water, which prevents the plants that grow in it being injured by drought; and it has a sufficient degree of porousness to allow superfluous moisture to percolate without making it too soft. All that is required for such a soil is a porous substratum of rock or gravel; and where this is not the case, sufficient underdrains must be made to produce the same effect. The clay soils in Britain are not in general of this fertile kind. They are of a compact nature which retains the water; and the various oxides and salts of iron which they contain are mostly injurious to vegetation. Hence they require expensive draining, and manuring, to render them productive. This has made lighter soils, which are more easily worked, to be generally preferred, although naturally less adapted to the growth of wheat; and the mode of cultivation of the light soils has advanced more rapidly towards perfection than that of the clays. Yet the latter will undoubtedly repay the outlay best, when once they are brought to a certain state of improvement. When clay soils are well drained, and when the effect of noxious salts has been removed by liming, burning, and frequent stirring, it will be found that a much smaller quantity of manure will produce a certain return in grass or corn, than on any light soil. The great difficulty is to choose the time when stiff clays are to be worked; and here it may be observed, that ploughing sometimes does more harm than good. When clay is wet, especially in the beginning of summer, and it is ploughed in the regular process of fallowing, the tough moist slice cut out by the plough is set on edge, and the sun bakes it into a hard mass like brick. In this state it is not improved by exposure to the air, which cannot penetrate this hard substance. It would be much better to plough out deep water-furrows with a plough made on purpose, and wait until the moisture is reduced by gradual percolation and evaporation; so that the plough should raise a slice ready to break and crumble as it is turned over. This should be done immediately before winter, and then the frost will so divide and mellow the soil that, provided it be kept free from superfluous water by under-drains and water-furrows, it will have the appearance of the finest mould when worked with the harrows in spring. To plough it again would be to spoil all. It should have received the necessary manuring in autumn, and be ready for the seed to be sown on this pulverised surface. The horses which draw the harrows or the sowing machines should be made to walk in the furrows, which should afterwards be deepened out with the spade, or by a plough constructed for the purpose. A free course and outlet should be formed for all surface water; for no maxim is more true than this, that stiff clays are never injured by a continuance of dry weather, unless they were in a wet state immediately before: the great means, however, of improving clay soils is thorough under-drainage [DRAINAGE]. The driest clay contains sufficient water to supply the roots of plants for a long time; but wet clay in drying and shrinking destroys the texture of the roots by mechanical pressure. This may be of use when weeds are to be eradicated, and in that case a different mode of proceeding may be recommended; but when good seed is sown, the clay should be in such a state as to crumble under the harrows, and it should not be too moist.

Fallowing for wheat is the old system on clay soils, and continues to be so in nine farms out of ten; but it often happens that in a wet season the whole advantage of the repeated ploughings is entirely lost, the land sown with wheat is neither enriched nor improved by all the tillage bestowed upon it, and is as full of weeds as it was when first broken up from the preceding stubble. The better system is to clean the land well in summer, after it has borne a crop of winter tares, which have been cut green or fed off by sheep in May or June, and to lay it up high and dry for the winter, after having given it the proper liming and manuring; to sow it with oats and grass seeds in spring, keep it in grass as long as is convenient, and break it up in autumn. Wheat may then be sown; or it may have the benefit of another winter's frost, and beans may be drilled or dibbled early in spring. After harvest, the bean stubble may be cleared with harrows or scarifiers, and the seeds allowed to vegetate; the plough will then destroy them. A good crop of wheat may be depended upon after this, if the land is in good heart; if not, it should have been manured for the beans: but if the grass was fed off the preceding year, and the land well managed before, it cannot fail to be in good heart. Clay land will bear a repetition of the same crops much oftener than lighter lands; but every scientific agriculturist knows the advantage of varying the produce as much as possible, making plants of different families succeed each other. The cereal grasses are of one family, which is the reason why wheat, barley, oats, rye-grass, &c., do not succeed so well after each other as after leguminous plants or clover, and that turnips, besides cleaning the land by the repeated hoeings given them, are so good a preparation for corn. A good rotation for stiff clays is yet a desideratum in agriculture; and although we will not affirm that fallows can be entirely dispensed with, we are persuaded that they might be separated by much longer intervals than is usually done. And if advantage is taken of early seasons, at least in the southern parts of the island, most lands may be kept clean by what is called a bastard fallow immediately after harvest, without losing a crop. We will go farther, and assert that instead of three crops in four years,

which is the common method and an improvement on the old system of two crops and a fallow, five might easily be obtained, especially if tares and *Trifolium incarnatum* are considered as crops. For example: 1. Oats or barley; 2. Clover; 3. Wheat; 4. *Trifolium* cut in May, and succeeded by spring tares, cabbages, or potatoes. Mangold wurzel is another green crop easily cultivated on clay soils. At all events the trifolium or winter tares may always be had in the year in which the land is to be cleaned by repeated ploughings; as they may be cut early in summer, and leave ample time for the operations.

The great disadvantage of clay soils in a moist climate like that of Great Britain, arises from an excess of water, and the obvious remedy is perfect draining of the subsoil. This is effected by numerous hollow drains judiciously arranged to convey the water to a proper outlet. [DRAINING.]

Clay is extensively used in many parts of England to improve light land, by being carried on the surface in considerable quantities, but this is chiefly where it approaches to the quality of marl, by having a considerable portion of calcareous earth in its composition.

The effect of burnt clay as a manure has been highly extolled, and not without some reason in particular situations. Clay by burning alters its nature; it becomes insoluble in water, and loses its attraction for it, becoming more sandy in its texture. The addition of it will thus improve a very strong retentive clay, tempering it and rendering it more porous. To burn clay, it is dug out in lumps and dried; heaps are made of these at regular distances in a field, with a small cavity in the centre, in which dry furze and brushwood are introduced. This being lighted, the fire is allowed to burn very slowly, and the smoke kept in by adding a sod or clod wherever it bursts out. When the heap is once burning, more clay may be added even without being dry, and the combustion goes on without other fuel. It must be so managed as to bake the clay without heating it too much; and when the heaps are cooled and opened the whole should appear pulverised, and of a red colour if oxide of iron exists in the soil. A coat two or three inches thick spread over a field and ploughed in will greatly improve its texture; but sufficient animal or vegetable manure must be added to make it fertile.

CLAY. Clays are more or less pure compounds of alumina and silic acid. [ALUMINA.]

CLEF (Fr. *clef*, a key), in Music, a character placed at the beginning of the staff, to give names to the lines and spaces, and determine the acuteness or gravity of each note.

There are three clefs—the *treble*, the *mean* (or *c* clef), and the *base*. The *Treble Clef* is now only placed on the second line, which it names *G*.

The *Mean Clef* gives the name of *c* to any line on which it is placed: it is called the *soprano clef* when placed on the 1st line, the *mezzo-soprano* when on the 2nd, the *alto*, or *contratenor*, or *countertenor*, when on the 3rd, and the *tenor* when on the 4th. By this contrivance the use of numerous ledger lines is avoided, and the music becomes more easy to read.

The *Base Clef* is now placed only on the 4th line, giving it the name of *F*.

The treble clef is appropriated to female and boys' voices, and to instruments the scales of which run high. Of the four kinds of *mean clef*, the first is used for female and boys' voices; the third and fourth for men's voices, also for the viola, the two higher trombones, and occasionally for the clarinet and violoncello. The *base clef* is appropriated to the lowest male voices, and to instruments the scales of which run deep.

In the 17th century the treble clef was used on both 1st and 2nd lines, and the base on both 3rd and 4th. The correction of so great an evil was a step towards simplification, and, in 1672, a distinguished mathematician (Thomas Salmon, M.A., of Trinity College, Cambridge) published his plan for a complete amelioration, by the abolition of all clefs, and substituting for them one universal character. The plan was simple and feasible; but it was at once violently, and successfully opposed by the musicians of the day, at the head of whom was Matthew Lock. Thus was strangled in its birth a rational attempt to remove much of the difficulty attending the practice of music. The *c* clef is now gradually falling into disuse, but we fear that its final rejection is not near at hand, and that a long time will elapse before other desirable reforms in music, calculated to remove many of the impediments to the practice of the art, will be accomplished.

CLEMENTINES is the name given to a collection of decretals and constitutions of Pope Clement V., which was published in 1308 under the title of '*Liber septimus Decretalium*,' being the seventh book in order of time of the collection of the decisions and rescripts of the

popes on matters of ecclesiastical discipline, and also on matters concerning laymen which then came within the cognisance of the ecclesiastical courts. [CANON LAW.] The first printed editions of the Clementines are those of Mainz, 1460 and 1467, fol.

CLEPSYDRA (κλεψύδρα, from κλέπτειν, ὕδωρ). Before the invention of pendulum clocks, it was not unusual in astronomical observations to measure time by the flowing of water, upon a principle which, in its most simple application, resembled that of the hour-glass, but which was varied by contrivances for accuracy or ornament. Such an instrument was used, up to the time of Galileo, by Tycho Brahé for instance; but as he does not describe it among his instruments, we may suppose that he hardly considered it to rank among the primary aids of an observer.

The Chaldeans, it is said, divided the zodiac into twelve equal parts, as they supposed, by allowing water to run out of a small orifice during the whole revolution of a star, and dividing the fluid into twelve equal parts, the time answering to each part being taken for that of the passage of a sign over the horizon. The authority for this story is Sextus Empiricus ('*Adv. Math.*' cap. 21), who adds, that they regularly used the instrument in finding their astrological data, and remarks that the unequal flowing of the water, and the variations of temperature of the atmosphere, would affect the accuracy of their results. Pliny mentions Scipio Nasica as the first who introduced clepsydras into Rome.

We might perhaps object to Sextus Empiricus as an authority on Chaldean usages; but a good presumption of the early use of clepsydras in India is afforded by the arithmetical treatise of Bhascara, written in the 12th century. The prediction at the birth of his daughter, Liliwati, was that she should die unmarried. The father determined to have at least one struggle against the prophecy, and accordingly procured a bridegroom and an astrological determination of a lucky hour. The girl remained in her ornaments near the clepsydra, watching for the moment when she and her parent might set fate at defiance. But at length it was ascertained that the hour was past; and on examining the clock, which should have prevented such a catastrophe, it was found that a pearl had escaped from the daughter's dress and closed the orifice through which the water should have flowed. The father, thus disappointed, said to his unfortunate daughter, "I will write a book of your name, which shall remain to the latest times." The Liliwati accordingly remains, and bids fair to realise the prediction. (Taylor's '*Liliwati*,' Bombay, 1816.)

In the account given by Vitruvius ('*De Architectura*,' lib. ix.), he attributes the invention to Ctesibius; but the instrument described is so complicated that we by no means suppose he intends to assert that this was the first application of the principle even at Alexandria. Some mode of measuring time by the efflux of water, however rude it might be, was used at Athens before the time of Ctesibius, as we see by various passages in Demosthenes. The instrument described by Vitruvius is an elaborate contrivance, which shows the hour, day, month, and sign of the sun. The astronomical clepsydra was rejected by Ptolemy on account of its imperfections, and it is not necessary to follow the moderns through the various modifications under which they have attempted to apply the principle. Such instruments continued to be common, as toys at least, until the middle of the last century.

If we suppose a clepsydra made of a glass cylinder, with a very small orifice at the bottom, and the apparatus being filled with water, the orifice to be opened, the upper surface of the fluid will not descend equally in equal times, according to the notion which Sextus Empiricus attributes to the Chaldeans. If the water be pure, and the orifice very small and unclogged, the following will be the law of descent. Ascertain first the whole time of emptying the cylinder: then in the fraction m of the whole time, the fraction $m(2-m)$ of the fluid will have discharged itself; or that same fraction of the whole height will have been fallen through. Thus in one-half the whole time of emptying, $\frac{1}{2}(2-\frac{1}{2})$ or $\frac{3}{4}$ of the whole fluid will have been discharged, while in $\frac{1}{4}$ of the whole time $\frac{1}{16}$ of the whole will have been discharged. It is totally out of the question to suppose that the ecliptic was so nearly divided into twelve equal parts as actually was done, by any such imperfect process; though it is not impossible that by keeping the clepsydra constantly full, or very nearly so, equal times may have been estimated by the discharge of equal bulks of fluid. Supposing the cylinder to be kept constantly full, it would discharge its own bulk of fluid in exactly one-half the time in which it would empty itself undisturbed.

CLERGY, a collective term, under which that portion of the population of a country is comprehended who are in holy orders. It is used in contradistinction to *laity*, which comprehends all other persons. Like most ecclesiastical terms, it is of Greek origin, the word κληρικὸς (clericus) having been used in the sense of "appertaining to spiritual persons" by the Greek ecclesiastical writers. From *clericus* comes the word *clerk*, which is still a law term used to designate clergymen, but which appears anciently not to have been confined to persons actually in holy orders, but to have been applied to persons possessed of a certain amount of learning.

The distinction of clergy and laity in the Christian Church may be considered as coeval with the existence of the Church itself; for in the apostolic period there were officers in the Church specially appointed to discharge the duties of pastors or deacons, and even, as many suppose,

bishops or overseers, who had the superintendence of various inferior officers. These persons, though they might not perhaps be entirely relieved from the ordinary duties of life so that they might devote themselves exclusively to their sacred office, yet must necessarily have been nearly so, and it is certain that they were nominated to their offices by some peculiar forms. Very early, however, the distinction became complete. The bishops, priests, and deacons of the Christian Church, each ordained to the office in a manner which it was believed the founders of Christianity appointed, and each supposed to have received a peculiar spiritual grace by devolution from the apostles and from the sacred founder of Christianity himself, soon formed a distinct body of men demanding to be distinguished by some particular appellation.

In all Christian nations the distinction has been recognised by the political authorities, who have allowed certain social privileges or exemptions to the clergy. No inconsiderable share of temporal power, extending not only over the members of their own body, but over the laity, has in most states been conceded to them. In the great German confederation the sovereign power in some of the states was vested in ecclesiastics; while at Rome there has been for many ages an elective monarchy of ecclesiastics, in whom all temporal as well as spiritual authority has been vested.

It is easy to account for the ascendancy of the clergy in the middle ages, and for the acquisition by them of so many valuable exemptions, and so much actual power. They were the best-instructed part of the population. The learning of the age was almost exclusively theirs; and knowledge, if it is not itself power, is at least a means of obtaining it. Besides this, they had a most powerful instrument with which to work upon the ruder minds of the laity, in the power vested in them of alone administering the sacraments of the Church, and of regulating alone under what circumstances those sacraments ought to be administered. This enabled them to win acquiescence in any favourite design, sometimes by gentle influences and sometimes by terror.

The history of almost every country of modern Europe presents instances of struggles between the laity and the clergy for power or privilege. Our limits will not permit us to enter on these, not even on the struggles of this kind in our own country, where they were as determined, and sometimes as fierce, as in any country of Christendom. All power in the clergy of England to erect an authority dangerous to the laity, or to secure to themselves political immunities or privileges inconsistent with the general good, was broken at the Reformation. The clergy of England then became but a fragment of a once great and well-disciplined body, dispersed through the whole of Christendom, which, when acting with common effort and putting forth all its strength, it had been difficult for any single temporal prince to resist with effect.

We shall take from Blackstone a short statement of the privileges which the law of England allows to the clergy. They are but a faint shadow of the privileges which the clergy enjoyed before the Reformation: A clergyman cannot be compelled to serve on a jury, or to appear at a court leet or view of frankpledge. He cannot be compelled to serve the office of bailiff, reeve, constable, or the like. He is privileged from arrest in civil suits while engaged in divine service. He could claim benefit of clergy more than once. [BENEFIT OF CLERGY.] Such are the legal exemptions. On the other hand, the clergy cannot now sit in the House of Commons, nor can they engage in any kind of trade, though sometimes clergymen have been brought within the scope of the bankrupt laws. It was held, even, that they could not legally be shareholders in a commercial company, but this restriction was removed in 1838 by the 1 Vict. c. 10. By the law as it stood previously to the 57 Geo. III. c. 99, they were not allowed to take lands to farm; but by that Act (s. 2) they are permitted (with the consent of the bishop of the diocese) to farm lands to the extent of 80 acres for a term not exceeding seven years.

The clergy meet by delegates in convocation at the beginning of every new parliament; and they have courts in which jurisdiction is exercised touching ecclesiastical affairs, and, till 1858, all causes testamentary or matrimonial, as well as those where the church's censures are directed against particular classes of offenders. To them also belongs the whole ecclesiastical revenue, with divers fees or customary payments, and to them also the whole regulation of the terms of admission to their order.

The three great classes of the English clergy are the bishops, priests, and deacons. To be admitted into each of those classes requires a peculiar ordination. This distinction is of an entirely different kind from that which arises out of office or appointment. Of this kind of distinction there is in the English clergy the archbishop, the bishop, the dean and canons of a conventual or collegiate church (some of the canons being in many instances invested with particular characters, as precentors, succentors, and the like), the archdeacon, the rural dean, dean of some church whose constitution is peculiar, the rector, the vicar, the curate in some chapels called parochial, the minister in some newly founded chapel, whether a chapel of ease or what is called a proprietary chapel, assistant ministers to aid the vicar or the rector in some churches of ancient foundation, and, finally, a body of persons called curates, who are engaged by the incumbents of benefices to assist them in the performance of their duties, but who are not dismissible at the caprice of the incumbent, nor

left by law without a claim upon a certain portion of the profits of the benefice.

These are the various offices in which the clergy of the Church of England are distributed. As the subject is of importance, and seems to be but imperfectly understood, we shall here briefly notice wherein lies the distinction of *rector*, *vicar*, and *curate*, to one of which belongs nearly every individual of the English clergy.

For this purpose, England must be regarded as divided into somewhat more than 17,150 small districts (returns were not made of a few), varying in extent, called parishes or parochial districts, according to the census of 1851. Each of these parishes or districts must be regarded as having its church, and one person (or in some instances more than one) who ministers divine ordinances in that church. This person, whose proper designation is *persona ecclesiæ*, enjoys of common right the tithe of the parish, and has usually a house and glebe belonging to his benefice. When this, the original arrangement, is undisturbed, we have a parish and its *rector*. But in the times before the Reformation it was a very common practice of the *patrons*, or persons who had the right to nominate the *persona* or rector, to give that right to some monastery or community of religious. Such community, instead of nominating some person as rector, would profess to discharge the duties of the parish by sending from time to time one of its own body to perform those duties, or by engaging some person at a stipend settled by themselves, to perform the duties, they taking the tithe and other profits of the benefice to the use of their house. Some few of the ancient parishes of England have thus been entirely stripped of their tithe and the other property out of which a resident minister might have been supported; but in nearly every instance the bishops interfered, and compelled the religious houses to settle some determinate share of the profits of those benefices upon a clergyman who should be fixed in the parish upon the nomination of the monastery, but no more removable than if he had really been the *persona* or rector. This person is called the *vicar*, *vicarius*, that is, one who stands in the place of another; and the other whom the vicar represented was in this instance the religious community, in whom vested the two characters of patron and rector.

The provision made for the support of the vicar varied in different parishes, but it was usually some fixed portion of the tithe with the oblations. The agreement, however, which was between the religious community and the bishop was arbitrary, and hence it is that we find the vicars so variously endowed. At the Reformation, whatever interest the religious communities possessed in the parishes was seized by the crown, and has since been either retained by it, or, what has usually been the case, has been sold to private persons, whence arises the class of the *lay impropriators*, who are, in fact, the rectors of the parish, the performance of the spiritual duties devolving on the vicar. *Curates* who are not merely assistants to a rector or a vicar are, in general, incumbents of churches in which no vicarage was ever ordained, or incumbents of chapels of foundation later than the era of the foundation of parishes, and endowed by the special bounty of particular persons.

CLERGY, BENEFIT OF. [BENEFIT OF CLERGY.]

CLERK IN ORDERS. [CLERGY.]

CLERK OF ASSIZE is an officer attached to each circuit, who accompanies the judges at the assizes, and performs all the ministerial acts of the court. He issues subpoenas, orders, writs, and other processes; draws indictments; takes discharges, and respites recognizances; files informations, affidavits, and other instruments, enters every *nolle prosequi*, records all the proceedings of the court, and enters its judgments. He is associated with the judges in the commissions to take assizes; and he is restrained by statute 33 Hen. VIII. c. 24, from being counsel for any person on his circuit. He was formerly paid by the fees charged upon the several official acts performed by him; but now, by the 15 & 16 Vict. c. 73, and 18 & 19 Vict. c. 126, clerks of assize and their officers are paid by salary, the fees receivable in respect of their duties being accounted for by them to the government.

CLERK OF THE CROWN IN CHANCERY, is an officer of the crown in attendance upon both Houses of Parliament, and upon the great seal. In the House of Lords he makes out and issues all writs of summons to peers, writs for the attendance of the judges, commissions to summon and prorogue Parliament, and to pass bills; and he attends at the table of the House to read the titles of bills whenever the royal assent is given to them. He receives and has the custody of the returns of the representative peers of Scotland, and certifies them to the House; and makes out and issues writs for the election of representative peers of Ireland and their writs of summons. He is the registrar of the Lord High Steward's Court for state trials and for the trial of peers; and he is also registrar of the Coronation Court of Claims.

In connexion with the House of Commons, he makes out and issues all writs for the election of members in Great Britain (those for Ireland being issued by the clerk of the crown in Ireland); gives notice thereof to the secretary-for-war, under Act 8 Geo. II. c. 30, for the removal of troops from the place of election; receives and retains the custody of all returns to Parliament for the United Kingdom; notifies each return in the 'London Gazette,' registers it in the books of his office, and certifies it to the House. By Act 6 & 7 Vict. c. 18, he

has the custody of all poll-books taken at elections, and is required to register them, to give office copies or an inspection of them to all parties applying, and to prove them before election committees. He attends all election committees with the returns of members; and when a return is to be amended in consequence of the determination of an election committee, he attends at the table of the House to amend it.

He is also an officer of the lord chancellor, as the holder of the great seal; and in this department makes out all patents, commissions, warrants, appointments, or other instruments that pass the great seal, except patents which are passed in the Patent Office. He administers the oaths of office to the lord chancellor, the judges, the serjeants-at-law, and all other law officers, and records the same in the books of his office. For these several duties he receives a salary of 1000*l.* a year. (7 & 8 Vict. c. 77; 'Parl. Report,' 455, Sess. 1844.)

The office of the Clerk of the Crown is commonly called the Crown Office; but there is also an office in the Court of Queen's Bench called the Crown side, or Crown office of the Court, of which there is a master and other officers.

CLERK OF THE HOUSE OF COMMONS, the chief officer of that House, is appointed by the crown for life, by letters patent. Upon entering office he is sworn before the lord chancellor "to make true entries, remembrances, and journals of the things done and passed in the House of Commons;" in which duties he is aided by the clerk-assistant and second clerk-assistant. These three officers are more commonly known as "clerks at the table." The chief clerk signs all orders of the House, endorses the bills, and reads whatever is required to be read in the proceedings of the House. He is also responsible for the execution of all the official business of the House, which is under his superintendence. In the patent he is styled "Under Clerk of the Parliaments to attend upon the Commons;" whence it is inferred that on the separation of the two Houses, the under-clerk of the Parliaments went with the Commons, leaving the clerk of the Parliaments in the Upper House.

(Hatsell, *Precedents*, vol. ii. p. 251; May, *Law, &c. of Parliament*; 4 & 5 Will. IV. c. 70.)

CLERK OF THE PARLIAMENTS is the chief ministerial officer of the House of Lords. His duties (which are executed by the clerk-assistant and additional clerk-assistant) are to take minutes of all the proceedings, orders, and judgments of the House; to sign all orders, to endorse bills, to swear witnesses at the bar, to wait upon the sovereign when the royal assent is given to bills, and to take the commands of the crown upon them; and to signify the royal assent in all cases, whether given by the sovereign in person or by commission. He is also sent occasionally as a messenger from the Lords to the Commons. Besides these and other special duties, he is charged with the general superintendence of the official establishment of the House of Lords. He is paid out of the Lords' Fee Fund, of which no account is ever given.

(May, *Law, &c. of Parliament*.)

CLERK OF THE PEACE is an officer attached to every county or division of a county, city, borough, or other place in which quarter-sessions are held; being the ministerial officer of the court of quarter-sessions. He is appointed by the *Custos Rotulorum* of the county, and holds his appointment so long as he shall well demean himself. In case of misbehaviour the justices in sessions, on receiving a complaint in writing, may suspend or discharge him, after an examination and proof thereof openly in the sessions; in which case the *Custos Rotulorum* is required to appoint another person residing within the county or division. In case of his refusal or neglect to make this appointment, before the next general quarter-sessions, the justices in sessions may appoint a clerk of the peace. (1 Will. III. c. 21, s. 6.) The *Custos Rotulorum* may not sell the office or take any bond or assurance to receive any reward, directly or indirectly, for the appointment, on pain of both himself and the Clerk of the Peace being disabled from holding their respective offices, and forfeiting double the value of the consideration, to any one who shall sue them. (Id. s. 8.) To give effect to this provision, before the Clerk of the Peace enters upon the execution of his duties he takes an oath that he has not paid anything for his nomination.

The Clerk of the Peace may execute the duties of his office either personally, or by a sufficient deputy approved by the *Custos Rotulorum*. He or his deputy must be constantly in attendance upon the court of quarter-sessions. He gives notice of its being holden or adjourned; issues its various processes; records its proceedings; and performs all the ministerial acts required to give effect to its decisions. During the sitting of the court, he reads all acts directed to be read in sessions; calls the jurors, and parties under recognizance; presents the bills to the grand jury and receives them again; arraigns prisoners, administers oaths, and receives and records verdicts. Whenever prosecutors decline any other professional assistance, he is required to draw bills of indictment.

In addition to these general duties he has other special duties imposed upon him by different statutes, in regard to the summoning of juries, the appointment of sheriffs and under-sheriffs, the custody of inclosure awards, orders for stopping up highways, documents required to be deposited with him under Acts of Parliament and standing orders of the Houses of Parliament, and other matters.

The Clerk of the Peace is paid by fees or by salary, by order of a

secretary of state, on the recommendation of the court of quarter-sessions, or (in boroughs) of the town council. (14 & 15 Vict. c. 55. By the 57 Geo. III. c. 91, and the 11 & 12 Vict. c. 43, the justices of the peace for the county, and the town council in boroughs, are authorised to settle a table of fees, to be approved by the secretary of state, which may not be exceeded by the clerk of the peace, under a penalty. If he take more than is authorised by such table of fees, he will also be liable to be proceeded against at common law for extortion, and to be removed from his office by the court of quarter sessions. The sessions cannot, however, compel the payment of these fees by summary process, nor detain the parties until they be paid, but the Clerk of the Peace is left to his remedy by action.

(Dickinson, *Quarter Sessions*; Burn, *Justice of the Peace*.)

CLERKS AND SERVANTS. [SERVANTS.]

CLIENT (Clien), apparently derived from the verb *cluo*, "to listen to," "to obey;" though Dr. Ihne thinks that the derivation of the word from *colere* (*cliens quasi colonus*) has a certain value, as serving to mark out what he maintains, in opposition to Niebuhr, to be the fact that the true clients supported themselves through their connexion with agriculture. From the origin of the institutions of ancient Rome, there appears to have existed the relation of patronage (*patronatus*) and clientship (*clientela*). Romulus, the founder of Rome, was, according to tradition, the founder of this institution. Ihne, however, endeavours to maintain that the clientage was not an institution belonging exclusively to Rome, called into life by the whim of a king, or the co-operation of peculiar causes, but that it existed among all Italian people, Sabines, Samnites, and Etrurians. (See 'Researches into the History of the Roman Constitution,' by W. Ihne.) The cliens may perhaps be compared with the vassal of the middle ages. Being a man generally without possessions of his own, the client in such case received from some patrician a part of his domains, as a precarious and revocable possession. The client was under the protection of the patrician of whom he held his lands, who in respect of such a relation was named patron (*patronus*), that is, father of the family, as *matrona* was the mother, "in relation to their children and domestics, and to their dependents, their clients." (Niebuhr.) It was formerly the opinion that every plebeian was also a client to some patrician; but Niebuhr, in speaking with reference to the proposition that "the patrons and clients made up the whole Roman people," affirms that the "assertion is one the validity of which is not to be questioned, save when it is carried too far. If we do not acknowledge that the plebeians were free, and overlook the nature of the commonalty, it is both false and destructive of historical truth; but it is perfectly true if applied to the period before the commonalty was formed, when all the Romans were comprised in the original tribes, each in his own house." In the later times of the republic the clients probably, for the most part, consisted of *liberti* and their descendants. Between the patron and his client there existed mutual rights and obligations. The patron was bound to take his client under his paternal protection; to help him in case of want and difficulty, and even to assist him with his property; to plead for him and defend him in suits. The client on his part was bound in obedience to his patron, as a child to his parent; to promote his honour, assist him in all affairs; to give his vote for him when he sought any office, to ransom him when he was made prisoner and not able to pay the ransom himself; and to contribute to the portion of the patron's daughter. The patron succeeded to his property when the client died without heirs; which was also the law of the twelve tables in the case of a freedman (Ulpian., *Fragn.*, tit. xxvii. § i., and tit. xxix. § i.) who died intestate and left no heir (*suus heres*). Patron and client were not permitted to sue at law, or give evidence against one another; and so sacred were the duties of the patron towards his client, that whoever trespassed against them was guilty of treason, and devoted to the infernal gods (outlawed), so that any one might kill him with impunity.

Originally patricians only could be patrons; but when, in the later times of the republic, the plebeians had access to all the honours of the state, clients also were attached to them.

The terms *patronus* and *libertus*, or even *patronus* and *cliens*, as used in the later years of the republic, and under the emperors, cannot be considered as expressing the same relation as the terms *patronus* and *cliens* in the early ages of Rome, though the latter relation was probably derived from the earlier one. When a foreigner who came to reside at Rome selected a patron, which, if not the universal, was the common practice, he did no more than what every foreigner who settles in a strange country often finds it his interest to do. The existing relationship at Rome between patron and client facilitated the formation of similar relations between foreigners and Roman citizens; the foreigner thus obtained a protector and perhaps a friend, and the Roman increased his influence by becoming the patron of men of letters and of genius. (See Cicero 'pro Archia,' c. 3, and 'De Oratore,' i. 39, on the 'Jus Applicationis;' Dionysius ii. 9, 10. See also Niebuhr, vol. i., p. 322, edition 1851, &c., and the references in the notes.

As a Roman client was defended in law-suits by his patron, the word client is used in modern times for a party who is represented by a hired counsellor or solicitor.

CLIMATE is a word which has been transplanted from the Greek into every modern European language. The Greek word *κλίμα* (from

κλίνω, to incline) seems originally to have been used to express the apparent inclination of the heavens towards the horizon; and it was afterwards used as a technical term in astronomy and geography to indicate generally the distance on the celestial sphere, as well as on the terrestrial globe, from the equinoctial line towards the poles.

The plural of this word, κλίματα (climata), however, was used in a somewhat different sense, and answered, in some degree, to our parallels of latitude. The Greeks supposed the celestial sphere to be divided into girdles or zones, parallel to the equator, and surrounding the whole sphere. They then endeavoured to ascertain through what stars the parallel circles forming the boundary-lines of such a zone were to be drawn, and what stars fell within the zone. The same division they afterwards applied to the terrestrial globe, ascertaining first the places through which the boundary-lines of the zones ran, and then determining at what distance from them the intermediate places were situated. These zones were called climata, or climates, and were used by them as we now use the degrees of latitude.

These climata of the Greek geographers however did not always embrace an equal number of degrees of latitude. The principle of the division into zones was the length of the longest days; and a difference of half an hour generally determined the breadth of one of these climates. For instance, one of the boundary-lines of a zone would run through the places in which the longest day had thirteen hours, and the other through those in which it was thirteen hours and a half. This was sufficient for their purposes in those parts of the globe where there was only a small number of places the position of which had been determined. But it was not sufficient for those parts where the number of places determined was greater, as in Greece and the adjacent countries. Here they gave a less width to the climate, allowing only a quarter of an hour for the difference between the boundary-lines of a climate. For instance, the southern boundary-line of such a zone would run through the places whose longest day was fourteen hours, and the northern through those in which it was fourteen hours and a quarter.

The greater exactness of modern astronomical observations has rendered this division of the globe useless, and we have substituted for it the notation by degrees of latitude. The Greeks, of course, made use of these climata as we do the degrees of latitude, to indicate in a general way the comparative temperature which a country enjoys by reason of its smaller or greater distance from the equator. Modern nations have adopted the term climate, but with somewhat enlarged signification. Climate, with us, not only implies the greater or less degree of heat which a country is subject to, but also the quantity of moisture in its atmosphere, and, in general, all the phenomena which affect vegetation, and render a country a fit abode for men and animals.

Heat and moisture, properly speaking, constitute climate; but the latter is dependent on the former, while that itself varies originally according to distance from the equator, and height above the level of the sea, the results of both co-ordinates being themselves subject to variation from other causes. The other phenomena, such as winds, electricity, &c., affect these constituents of climate; but they require a separate consideration, as modifiers of it, according to the view which we take of the subject.

We may observe, that those places where a high temperature is combined with a great quantity of moisture, are the most fertile, and display the most luxuriant vegetation, provided the surface is not formed of naked rocks; but even the solid rocks will in time yield to the combined influence of heat and moisture, and be clothed with a rich vegetation; though, on the other hand, in temperate climates at least, certain igneous rocks, of which those of the extinct volcanic region of Central France are examples, remain undecomposed and almost devoid of vegetable covering for an indefinite period. And on the Peak of Teneriffe, the lavas resulting from countless ages of volcanic action, have not sensibly disintegrated; here, however, the atmosphere is arid, and the effective clouds are far below.

The latitude of the place is generally considered as the principal circumstance in determining its temperature. It is laid down as a fact, that countries lying under the equinoctial line or close to it are subject to the greatest comparative heat, which constantly decreases with the increase of distance from that line. This general rule must be admitted to be true for all the countries which lie between the tropics and the pole; but it may be questioned how far it is true of the countries within the tropics. A glance at a globe or sphere shows that the sun at the end of the first month after the equinox has already advanced 12° of latitude towards the tropic; but in the second month it traverses only 8° . At the end of the second month it is consequently 20° from the equator. There remain therefore only $3\frac{1}{2}^{\circ}$ to be traversed in the third month. The sun recedes from the tropic in the same way. It passes the first month through $3\frac{1}{2}^{\circ}$; the second through 8° ; and the third through 12° of latitude. Hence it is evident, that at all places between 20° and $23\frac{1}{2}^{\circ}$ of latitude, the solar rays during two months fall at noon either perpendicularly, or at an angle which deviates from a right angle only by $3\frac{1}{2}^{\circ}$ at most. If we take a place intermediate between 20° and $23\frac{1}{2}^{\circ}$ of latitude, the solar rays must fall on it during two whole months, either perpendicularly, or in a direction still less removed from the perpendicular than in the former case. On the other hand, when the sun passes the equator, two places on which the

vertical rays of the sun fall on two consecutive days are nearly $\frac{1}{2}^{\circ}$ of latitude distant from one another; and a place situated exactly under the equator has only during six days the sun as near its zenith as the above-mentioned places near the tropics have it during two whole months. We might therefore presume, that the summer heat of the latter position must be much greater than that of places near the equator. This degree of temperature must be increased by the greater length of the longest days, which near the tropic are $13\frac{1}{2}$ hours; but at the equator are always of the length of 12 hours.

This reasoning is not contradicted by experience. The countries in which the greatest degree of heat is experienced in the northern hemisphere, lie near the tropic of Cancer. They are the countries on the banks of the Senegal, the Tehama of Arabia, and Mekran in Beloochistan; tropical Africa, however, being the hottest region of all. The ancients were not unacquainted with these facts; and one of their most ingenious inquirers, Posidonius, was so struck by the peculiarities of the countries near the tropic, that, for the purposes of physical geography, he wished to consider them as forming a particular zone, different both from the equatorial zone and the temperate zone, and separating these two in the form of a narrow belt. He observes that these countries are characterised by the aridity and sterility of their soil, and that no rain falls there, while the regions nearer the equator, having abundance of rain and moisture, are exceedingly fertile. (Strabo, ii.)

Though the mean temperature differs greatly in countries lying in different degrees of latitude, the most intense degree of heat which is experienced in all countries between the equator and 60° of latitude is nearly equal. The thermometer rises almost every year at St. Petersburg to above 90° ; and it is observed that even on the coast of Guinea, and on the banks of the Senegal, it rarely exceeds 95° . There are certain instances in which it has attained a much higher degree. Dr. Coulter observed it at 140° on the banks of the Rio Colorado ($32^{\circ} 30'$ N. lat.); but such exceptions must be ascribed to local circumstances, especially to the reflection of the solar rays from an arid and sandy surface.

The general rule, derived from geographical position, as to the distribution of heat over the surface of the earth, is subject to many exceptions, arising from local circumstances. But none of these local circumstances probably affect it so much as the elevation of the surface. It is a well-known fact, that near the tropics and the equator there are mountains which, owing to their great elevation, are covered with snow all the year round. The heat experienced in a given place not only depends on the greater or less obliquity of the rays of the sun, but also on the greater or less column of the atmosphere. The column of air is greatest on the surface of the sea and in such countries as are nearly on a level with it. The higher we rise above this level the more the air is rarefied, and the degree of heat due to the solar rays decreases. Thus we at last arrive at an elevation where the heat, even under the equator, is insufficient to melt the snow. As the density of the air and the intensity of the heat continually decrease as we rise higher, some attempts have been made to determine the law of the decreasing temperature. Alexander von Humboldt, who made a great number of observations on the steep declivities of the Andes near the equator, came to the conclusion that the thermometer of Fahrenheit descends one degree when we rise 343 feet above the level of the sea, and one degree for every 343 feet more. Thus the thermometer may be used to determine in a rough way the heights of mountains or of elevated plains. The calculations of Humboldt, however, are only founded on observations made in the intertropical countries, and it is supposed that the same law will not be applicable in all its extent to places situated without the tropics. Dr. Joseph Dalton Hooker, F.R.S., from contemporaneous observations made in East Nepal, N. lat. about 28° , altitude 10,385 feet, and at Calcutta, found 1° Fahr. for every 309 feet of elevation.

As already observed, at a certain height above the surface of the sea the heat caused by the solar rays is too feeble to melt the snow and ice. This limit has been called the snow-line, or line of perpetual snow, or line of perpetual congelation. This snow-line does not occur in all places at the same elevation, but is dependent on the mean temperature in summer. In warm countries it is consequently found at a much higher elevation than in cold countries. It has been ascertained by numerous observations, that in the Andes of South America, near the equator, the summit of a mountain rising to less than 16,000 feet does not attain the snow-line; but in Norway, in 76° of lat., mountains with an elevation of 2900 to 3350 feet are always covered with snow, as Professor James Forbes has shown; and in the southern hemisphere the line of perpetual snow in the Straits of Magalhaens (52° S. lat.) is about 3390 feet above the sea. Nowhere in the Northern Hemisphere does the snow-line descend to the level of the sea, the intensity of the summer heat during the period of perpetual day effectually thawing the soil, though only to a trifling depth, and raising upon its surface a certain amount of brief vegetation suitable for the support of arctic animals. In the Southern Hemisphere, however, the temperature of which, as a whole, is greatly inferior to that of the Northern, the snow-line attains the level of the sea itself (according to Sir James C. Ross, as cited by Professor Forbes) in the Antarctic regions, at a latitude between 67° and 71° , under which, in Norway, forests still grow, and even corn in some sheltered places. Numerous observations made on

the mountains of Europe, combined with those made by Humboldt in South America, suggested the idea that the snow-line forms a regular

curve (north and south) on the surface of the earth, in the following way:—

But more recent observation has shown that we are still very imperfectly acquainted with the laws by which this important boundary-line in the atmosphere is determined. Mr. Pentland ascertained, by a great number of observations, that in the Andes of South America, between 14° and 17° S. lat., the snow-line does not occur on mountains below the height of 17,000 feet. Poeppig, in traversing the Andes, near 11° S. lat., found that here also they were free from snow

at an elevation several hundred feet higher than the snow-line under the equator. Agreeably to these facts, and to a generalisation of Von Buch which includes them,—that the temperature of the summer months determines the elevation of perennial snow,—the snow-line would thus be represented, not by a curve of continuous curvature, but by one of this form:—

These observations on the elevation of the snow-line above the level of the sea, are however only applicable to mountains which rise with a steep ascent, and are not contiguous to table-lands. High table-lands have a higher temperature than isolated mountains of the same height. Humboldt observed that the elevated plains on which the towns of Bogotá, Popayan, Quito, and Mexico are built, have a much warmer climate than they would have if elevation above the sea were the only element that determined the temperature when the latitude is given. In comparing the mean temperature of these plains with that of the adjacent coast, he found that the thermometer, instead of descending one degree for every 343 feet, had only sunk so much for every 400 feet of perpendicular elevation. He thinks that this difference may be accounted for by supposing that the temperature of the atmosphere, under these circumstances, is considerably raised by the reflection and radiation of the sun's rays from a plain of considerable extent. This supposition is confirmed by the circumstance of the different heights at which the snow-line occurs on the southern and northern declivities of the Himalaya Mountains. On the southern declivity of that range, which rises rapidly from the low plains of the Ganges, Mr. Webb found the snow-line at an elevation of about 13,000 feet, corresponding pretty well with its latitude (about 30°); but on the northern declivity, which is about a degree farther north, the snow-line ascends to 16,000 feet, an elevation which corresponds to that found under the equator. On this side, however, the range, though very steep, does not descend to a low country, but terminates in an immense plain, the surface of which is about 10,000 feet above the level of the sea. The great difference between the elevation at which the snow-line occurs on the two declivities is thus partly to be explained by the difference in the height of the plains which are respectively contiguous to them; but in part, also, by the excessive dryness of the climate of Tibet, on the northern side of the range.

Captain Gerard gives from 18,000 to 19,000 feet as the altitude of the level of perpetual snow on the mountains of the Tibetan table-land north of the upper valleys of the Indus and Sutlej. From the more recent observations of Dr. Hooker, given in his 'Himalayan Journals,' it appears that on the Donkia Mountain (23,176 feet high), in Sikkim, 28° N. lat. very nearly, the elevation of the snow-level is not less than 19,000 feet; and he is of opinion, that 40 miles further north (in Tibet), its altitude is probably 20,000 feet.

This subject will be resumed in the article SNOW, PERENNIAL. Its relations to that of climate in general have been thus summarily stated by Prof. Forbes, in his work on Norway, pp. 205–206: "The occurrence of perpetual snow at a certain height above the sea, in even the warmest regions in the globe, has in all ages excited the curiosity of geographers and naturalists. Regarded at first as a very simple indication of the depression of temperature as we ascend in the atmosphere, it has been carefully studied and applied (often erroneously) to the determination of climate. Closer examination has shown that the presence of perennial snow—in other words, a predominance of all the causes tending to its accumulation over those which tend to its waste or fusion—is, indeed, a very complicated fact, and cannot be taken as the simple expression of any one of the elements of climate. The snow-line is far from having invariably a mean temperature of 32°, as was at one time supposed. Under the equator it is about 35° [in the Sikkim Himalaya probably 20°, according to Dr. Hooker]; in the Alps and Pyrenees about 25°; and in latitude 68°, in Norway, it is (according to Von Buch) only 21°. . . . The mean temperature of the snow-line diminishes towards the Pole, because, for a given mean temperature of the whole year, the summer is far hotter in proportion. Also, places at which the temperature of the summer is low, are those which have a moderated or coast climate; but there also the fall of rain and snow is most abundant, whilst in excessive or continental climates the precipitations are comparatively small."

Temperature is still affected by such circumstances and phenomena as the nature of the soil, the prevailing winds, the quantity of moisture, the electrical state of the atmosphere, and the physical character of the adjacent countries and seas.

Where the soil has been to a great extent cleared and brought into cultivation, the air is much drier and warmer in summer than in those tracts which, for want of cultivation, remain covered with swamps and marshy grounds. This, according to Darby, is the case in the cultivated parts of the United States, in which he asserts, contrary to the vulgar notion, that in the cleared and cultivated tracts the summer temperature has been raised, and that of winter diminished. The latter circumstance would seem a natural consequence of clearing the surface and exposing it during the winter months to the full influence of the north-west winds. In fact, as the country becomes more open, the range of the thermometer increases. As far as we know, no attempts have been made to ascertain to what amount such differences in the soil affect the temperature of a country, though our knowledge seems to be quite sufficient to assign the reasons for the existence of such a difference.

The effect of the winds on the temperature of a place is still more obvious. It is a common observation, that the thermometer is more or less raised or depressed by every change of the wind. But there is a great difference in this respect between the lower and higher altitudes. In the former, a change of wind rarely raises or depresses the thermometer more than a few degrees; while in the higher latitudes it frequently happens that in a few hours a change of ten or twelve degrees, and even more, takes place. Captain Scoresby mentions an instance of this near the polar ice. On a sudden veering of the wind to the north, the thermometer fell, in sixteen hours, 34 degrees, from + 32° to – 2°. But changes as great as this, so far as such changes are measured merely by degrees, occur in the United States of North America, at some distance from the Atlantic. Again, even in the lower latitudes, the change of the wind has a greater effect on the temperature on high table-lands than on low plains. Mr. Dunn states, that on the table-land of Guatemala, it sometimes, though very rarely, happens, that during the period of the northern winds a cold current produces a difference of 20 degrees in a few hours. A similar phenomenon has never been observed on the low coasts between the tropics.

It is a very common observation, that both cold and heat are more intense when the sky is clear than when it is overcast with clouds. Hence it may be inferred that countries, whose atmosphere is more loaded with clouds and vapours than that of others in the same parallel, must have warmer winters and colder summers. This difference is observed all over the world, and from it partly arises the difference of climate in maritime and continental countries. It is even observed in countries which are at no great distance from one another, as in England and Holland. In England, the mean temperature of the summer and winter is said not to differ more than about 22 degrees of Fahrenheit, while on the opposite shores of Holland it amounts to 27 degrees, the winters there being a little colder and the summers somewhat warmer than with us. On this, however, we must observe that there is no very great propriety in comparing the mean temperature of a country of the form and position of England with one of the form and position of Holland. If two points under the same latitude, and both near the sea, were taken on the opposite coasts of England and Holland, the difference, whatever it might be, would obviously be owing to the difference in the tracts of country contiguous to the respective places, to the winds, and to the hygrometrical state of the atmosphere. Before any safe conclusion could be drawn, all these conditions should be known. There appears no doubt, however, that the difference in the mean temperature of the two seasons increases as we proceed farther east in the European continent; and it

is equally certain that it depends mainly on the hygrometrical state of the atmosphere, which again in a great degree depends on the winds.

Since the time of Franklin, the attention of observers has been drawn to the effects which the temperature of one country has on that of contiguous countries. In calm weather that effect is probably so small as not to be perceptible. But whenever a wind is stirring, it brings the colder or warmer air from one country to the other, and thus lowers or raises the temperature of that country to which it blows. This effect is very perceptible on the eastern shores of England, with respect to the easterly winds. In the latter part of the spring or early in summer, these winds, before they reach England, pass over the still chilled and damp surface of the great plain of Northern Germany, and blight the already advanced vegetation of our eastern counties. On the contrary, in autumn the same winds pass over a sandy soil, which during the summer has acquired a considerable degree of heat, and the air brought over by them is warm enough to raise the thermometer several degrees. A still more remarkable instance is mentioned by Pœppig, in his 'Travels through Chile, Peru, &c.' In the southern districts of Chile, the eastern winds, called there *los Puelches*, when they blow in spring (September) are so cold that they depress the thermometer in a short time 15 or 18 degrees; but towards the end of the summer (February) they raise it nearly as much. He attributes naturally enough the first effect to the chain of the Andes being covered with deep snow during the spring, and the second to the high temperature to which the air upon the sandy plains of the Pampas of Buenos Ayres is raised during the summer months.

Considering the great effect which the temperature of countries contiguous to one another exercises on their respective climates, we may presume that a similar effect is produced by seas similarly situated. This has been long ago shown by the observations made on the regular change of the land and sea breezes in warm countries, and by the explanation of this phenomenon, which is obvious and simple. But it has only been recently ascertained, that the proportion between the temperature of the sea-water and the atmosphere above it is not everywhere the same, but that in some parts the sea-water is warmer than in others under the same latitude. Now the temperature of the water must in some degree affect the temperature of the atmosphere, and this atmosphere, when brought into contact with the air of the land by the winds, must produce a change in its temperature. This consideration may sufficiently explain why the countries round the Mediterranean enjoy a much milder climate than all others placed under the same parallel. It is now ascertained that the temperature of the water of the Mediterranean Sea is from 4° to 5° higher than that of the Atlantic in the same parallel. This may perhaps lead us to the explanation of the greatest anomaly of climate which exists on the globe—we allude to the great difference of temperature existing between the western countries of Europe and all the other countries of the globe lying in the same parallel.

Those who had the first opportunity of observing the difference in temperature between western Europe and the eastern coasts of North America were natives of western Europe, and of course they considered the climate of their own countries as constituting the rule, and that of North America as the exception. They accordingly attempted to explain this phenomenon by a reference to some peculiarities which characterise North America as a continent, such as the increase of its breadth towards the poles, the stretching out of the continent so far to the north, its large rivers and lakes, &c. But when the temperature of Asia and the eastern countries of Europe was ascertained by observation, it appeared that their temperature differed as much, and in many places still more, from that of the western countries of Europe than North America does. The climate of America may therefore be considered as the rule, and that of Europe the exception. Still the question remains, to what peculiar circumstance it is owing that the temperature of Western Europe differs from that of America and the countries lying farther east in the same latitude by 8° or 10°.

We venture to offer an opinion that the Gulf Stream is the most active, if not the only, cause in producing this difference. This remarkable current stretches across the Atlantic between Cape Hatteras, in North America (35° N. lat.), and the Azores, forming nearly in the middle of the Northern Atlantic a lake of warm water, which, according to the calculations of Major Rennell, is not inferior to the Mediterranean in extent. The temperature of its water is from 3° to 10° higher than that of the surrounding sea. The temperature of the superincumbent air is likewise several degrees higher than it is farther to the west and south, but less so when compared with those portions of the Atlantic which lie farther to the east and north-east. We think that this last difference is due to the strong gales which are almost continually experienced in navigating the Gulf Stream, but more especially on its borders; they blow most frequently from the south-west and west. Winds blowing from these quarters are by far the most prevalent in the Northern Atlantic, and it is observed that even on the coast of Western Europe they still preserve the character impressed upon them by the gales of the Gulf Stream. They do not blow equally like the other winds, but in abrupt gusts, with short intervals of calm. These winds appear to waft the warmer air of the Gulf Stream over the whole of the coasts of Western Europe from Cape Finisterre as far as North Cape; they even penetrate through the wide gate between the Harz mountains and the Scandinavian ranges into

the recess of the Baltic, and their effects extend to the very plains of Russia, where they are met by the prevailing north-eastern winds and stopped. All the countries within the range of these winds enjoy a much more favourable climate than those to which they do not extend.

It may here be objected, that as the Gulf Stream approaches much nearer the coast of North America than that of Europe, and as the temperature of its water is also highest there, such an effect as is here described should rather apply to the New than to the Old Continent. But, in the first place, the Gulf Stream along the coast of America is of comparatively inconsiderable width, being opposite Charleston only from 60 to 63 miles across: and, secondly, its waters in their whole course along that coast lose very little of their temperature. At Cape Hatteras, after a course of 900 miles, the stream has only lost 3° Fahr. of warmth. From this point it turns to the east, and the decrease of temperature begins to be somewhat greater. Yet even opposite the great bank of Newfoundland, after a course of 1300 miles through 15° of latitude, its waters have lost only 5° Fahr. of warmth, and the temperature in this part is from 8° to 10° above that of the adjacent seas. The decrease of temperature begins to be most considerable about the middle of the Atlantic. Now, when we consider that on the eastern coasts of North America likewise the western and southern winds prevail, it follows that by far the greatest portion of the warm air derived from the evaporation of the Gulf Stream must come to those countries which lie to the leeward of these winds. The parts of North America, however, to the east of the Appalachian range, seem also to feel in some degree the heated air of the Gulf Stream; since it has been proved by Darby that they have a temperature by several degrees higher than the parts in the same latitude to the west of that range.

Another remarkable difference in temperature occurs in the countries which form the most southern part of the American continent. Humboldt has compared a considerable number of observations, from which it appears that south of 48° the mean temperature of South America is from 12° to 18° lower than that of those parts which lie in the same latitude in other meridians. North of 48° S. lat. this difference is still considerable, but it gradually diminishes as we approach the tropics. At about 30° it seems to disappear entirely. The greater cold of the antarctic regions had been recognised before. It was conjectured by Captain Cook to be due to the existence of a large tract of land between 70° S. lat. and the pole. This was singularly confirmed by the investigations of Sir James C. Ross in 1841, who found Victoria Land, extending from 71° to 79° S. lat., skirted by a great barrier of ice; and the land itself, ranging in altitude from 4000 to 14,000 feet, entirely covered with snow.

Many persons suppose that the peculiar form of South America, which narrows towards the south, and stretches out in the form of an acute angle, may be sufficient to explain this phenomenon; but this diminution of the surface of the land should rather have an opposite effect, and the true cause we have no doubt is to be found in the fact last stated.

There are other circumstances, besides those enumerated, which affect the general temperature, but their influence is confined to small tracts. Thus the temperature of some places is considerably raised or lowered from their being situated on the southern or northern declivity of a high range, or in a narrow valley, or from their being entirely or in a great part surrounded by water. Even the existence of large forests has some influence on the temperature of contiguous places. But as the influence of such circumstances is local, it may be sufficient here to indicate it.

The circumstances which tend to increase or to depress the general temperature of a country being so numerous, and their effect (in producing which several of them often co-operate) being in some instances very great, it often happens that the actual temperature of a country differs considerably from that which might be inferred from the latitude in which it lies. To show therefore what countries, situated under different parallels, have an equal or nearly equal temperature, the isothermal lines, or lines of equal temperature, have been introduced. [ISOTHERMAL LINES.]

The second chief constituent of climate, the moisture of the air, appears under the form of rain, vapour, fog, and dew. We shall limit our observations to rain, in this article.

There are extensive tracts of this globe on which a drop of rain is never known to fall, or only at intervals of many years, and then only in small quantities. These countries are always found near the tropics, sometimes extending on both sides of these circles, but often only on the side towards the poles, which circumstance is probably to be ascribed to local peculiarities. These countries may be said to run like two belts round the globe, dividing the countries on each side of the equinoctial line from the temperate zone, as Posidonius very correctly stated. It is only where mountain-ranges exist, that these belts of rainless regions are interrupted. Beginning with the Old Continent, we find in Africa the Sahara or Great Desert, on the southern borders of which the rains cease at about 16° N. lat. and on the north begin at about 28°. Proceeding farther east, the southern rains cease in the countries on the banks of the Nile between 18° and 19°, and the northern begin between 27° and 28°. Passing the Gulf of Arabia we find the Tehama, or low coast of Arabia, which is destitute of rains; but we do not yet

know how far to the south or north the rainless region extends. The high table-land which backs this coast on the east is said to have annually some rain, but we have no account of this region on which we can rely; it may be that it owes this advantage to local peculiarities, especially to its elevation. Farther east the rainless region extends through Meckran, a province of Beloochistan, the desert of that country, and over the delta of the Indus. Here it appears not to comprehend more than 4° of latitude. From this point it turns to the north-east and extends to 30° N. lat., comprehending the Indian desert to the very base of the Himalaya mountains. Behind this range extends the high table-land of Tibet, which also has no rain. But at the eastern extremity of the Old Continent, in China, there is no rainless region, which may perhaps be owing to the circumstance that all the parts of China between 22° and 30° N. lat. are traversed by the high mountain chains of the Nan-ling and Yoo-ling, and consist of a continual succession of ridges and valleys.

That part of Southern Africa, on the shores of the Atlantic, which extends to the north of the Gareep, or Orange River (between 24° and 28° S. lat.), is said to be a sandy desert, with little or no rain. Towards the Indian Ocean, Africa is traversed by several mountain-ranges, and consequently has there a somewhat moister climate. Australia also appears to be subject to the same disadvantages. The long droughts, sometimes continuing several years together, which occur in New South Wales, indicate that a great portion of Australia must be reckoned among the countries which are entirely or nearly destitute of rain.

In America the rainless region near the tropics is less distinctly marked, probably on account of the comparatively narrow width of that continent near the tropics, and other local peculiarities; yet such a region exists in both hemispheres. In the northern it seems to occupy the coast of the Gulf of Mexico, between 24° and 26°, and to extend westward, comprehending the arid plains of Monterey and Chihuahua, till it reaches the northern portion of the Sierra Madre Mountains, whose northern extremity it surrounds. It then stretches along both banks of the Rio Gila to the Gulf of California, where it however does not terminate, as the peninsula of California has no rain north of 23°. The countries of South America, near the tropic of Capricorn, rise suddenly from the Atlantic Ocean to a considerable height, and take the form of high table-land, traversed by mountain ridges. These parts of course are not without rain; but nearly midway between both oceans the country sinks considerably lower, and the Grand Chaco or Great Desert occurs, in which rain seems to be very rare. This extensive plain is divided from the Atlantic by a mountainous country, and from the Pacific by the high range of the Andes. In both these mountainous regions rains are frequent; but on the coast of the Pacific, though it presents a very uneven surface, not a drop of rain is known to fall all the year round between 23° and 27° S. lat. This barren tract consists of the Chilese department of Copiapó and the Bolivian province of Atacama.

These two belts of rainless regions, which on the land are frequently narrowed or interrupted by local circumstances, have a more distinct character on the ocean. Rain seldom falls within the range of the trade winds, except on their very borders, both towards the region of the calms and towards that of the variable winds. [CALMS.]

Between the two belts formed by the rainless regions are situated those countries which are subject to the equatorial rains. The ocean also has these rains in a small degree in those parts which constitute the region of calms. Here the phenomena of the atmosphere succeed one another with great regularity. The sun rises in a cloudless sky; towards noon some faint clouds appear near the horizon, which rapidly increase in extent and density, and are soon followed by thunder and violent gusts of wind, accompanied by heavy rains of short duration; towards evening the clouds disappear, and the sun sets in a serene sky of a deep blue hue. It does not appear that this state of the weather is at all affected by the seasons.

Those parts of both continents which lie on each side of the equator between the rainless regions have the greatest quantity of rain, and this occurs at certain periods of the year, whence these rains are called periodical rains. The season of the rains depends on the position of the sun. It begins some time before the sun reaches the zenith of a place, and continues for some time after it has passed it; hence the rainy season varies with the difference of latitude. Though the observations which are requisite to determine this point are far from being sufficiently numerous, it would appear that those countries which are near the equator are never for many days altogether without rain, and that there the rainy season, which occurs when the sun passes over the zenith, is only distinguished from the other parts of the year by a greater continuance and a greater abundance of the rains. In the countries more than 5° of lat. distant from the equator, the dry and wet seasons are distinctly marked. The rains begin either immediately or not many days after the sun in its progress towards such a place has passed the equator. They are heaviest when the sun approaches the zenith of the place, after which they continue with less abundance for an equal or even a longer time. In general the rains are more abundant in the first than in the second half of the season.

Countries that lie between 5° and 10° of lat. have commonly two rainy and two dry seasons. The greater rainy season occurs when the sun in its progress to the nearest tropic passes over the zenith, and

lasts from three to four months. The less rainy season occurs when the sun on its return from the nearest tropic approaches the parallel of the place. The rains then last only from six weeks to two months, and are much less abundant and continual. Countries more than 10° or 12° from the equator have only one rainy and one dry season; the first begins when the sun approaches the nearest tropic, and ends some time after, when, in its course from the tropic, it has passed the parallel of the place. It lasts from four to six months. Such is the course of the rainy and dry seasons in these countries, when their regularity is not disturbed by local circumstances, which sometimes effect considerable changes. The most remarkable deviation from this order occurs in India, where the period of the rainy and dry season is not regulated by the position of the sun, but by the change of the monsoons.

The periodical rains differ from the variable rains, which occur in the countries that lie without the tropics, not only in the greater regularity of the time at which they fall, but also in their abundance. The quantity of water which pours down between the tropics in one hour is often greater than that which falls in these latitudes in three or four hours. There is however an erroneous opinion prevalent respecting these rains: it is generally supposed that they continue for many days without interruption, but this is not the case: a day in which the rains fall without interruption from morning to evening is of much rarer occurrence between the tropics than with us; the sun usually rises in a cloudless sky: two hours before noon the clouds begin to appear, and at noon the rains set in. They then frequently pour down in torrents for four or five hours; but towards sunset they cease, the clouds suddenly disappear, and not a drop descends during the whole night. As the abundant rains, especially when the rainy season sets in, frequently cover the level and low country a foot deeper with water, the atmosphere of such tracts is continually loaded with vapours and exhalations during that period, which render the stars invisible at night, and are doubtless a principal cause of the unhealthiness of those countries.

The parts which lie between the rainless regions and the pole are subject to the variable rains. There is not a single day in the year in which it has not rained, or may not rain, and the rains are perhaps as common in the night as in the day. There are certainly differences, both in the quantity and in the time of the rains in these countries; but these differences can only be ascertained by comparing long sets of exact observations; and such exact observations are still wanting, except for the western parts of Europe. Comparing these observations, one would suppose that the countries south of 45° N. lat., with few exceptions, have also a kind of rainy and dry season, the former occurring in autumn and winter, and the latter in spring and summer. In summer frequently two or three months pass without a single drop of rain falling. In the countries north of 45° such a difference is not observed; there the greatest quantity of rain seems to fall in the summer, except in England, where the spring and summer are the driest seasons. The quantity of rain however decreases as we advance from the shores of the Atlantic to the inland parts of the European continent. The rains become again more abundant when we reach the plains of Eastern Europe, near Petersburg and Moscow, which may perhaps be owing to the circumstance, that here the winds proceeding from the Gulf Stream meet those which blow from the Ural Mountains and the great sandy deserts. These rules, derived from observations made in Europe, will probably not hold good for other parts of the globe, because the temperature of Europe forms, as we have observed, a great anomaly. Accordingly we find that meteorological observations made in the United States are far from confirming these rules. [ISOTHERMAL LINES, METEOROLOGY, RAIN, REFRIGERATION OF THE GLOBE, SNOW, TEMPERATURE, WEATHER.]

CLIMAX (*κλίμαξ*, a step or ladder), commonly called a figure of rhetoric, but properly only an artifice of style; for a figure or trope is a use of words in some other than their natural or literal sense. In accordance with the primary meaning of the Greek word, a climax in composition is a mode of expression by which the writer mounts, as it were, from one clause to another, as if he were climbing a series of steps. In other words, each clause expresses a higher degree of that which is stated in the preceding clause. The three words which Suetonius records to have been uttered on the occasion of one of his victories by Julius Cæsar—"Veni, vidi, vici," form a climax. The following sentence addressed by Cicero to Cataline is another: "Nihil agis, nihil moliris, nihil cogitas, quod ego non audiam, non videam, planeque sentiam." (You do nothing, you attempt nothing, you conceive nothing, which I do not hear, which I do not see, nay, which I do not even feel.) "A gradual progress from small to great," observes Lord Kames ('Elements of Criticism,' chap. iv.), "is not less remarkable in figurative than in real grandeur or elevation. Every one must have observed the delightful effect of a number of thoughts or sentiments, artfully disposed like an ascending series, and making impressions deeper and deeper; such disposition of members in a period, is termed a *climax*." In another passage he makes an attempt to explain the effect asserted to be thus produced. "If a number of objects of the same kind," he says (chap. xviii. § 2), "differing only in size, are to be ranged along a straight line, the most agreeable order to the eye is that of an increasing series; in surveying a number of such objects, beginning at the least, and proceeding to

greater and greater, the mind swells gradually with the successive objects, and in its progress has a very sensible pleasure. Precisely for the same reason, words expressive of such objects ought to be placed in the same order." The effect of a climax would seem to be more simply accounted for by the consideration of the state into which the mind of a reader or hearer is necessarily thrown by an emphatic assertion in a vehement or impassioned discourse; he naturally expects that the next assertion, if another is to follow, will involve something still stronger or more exciting—that it will constitute some addition to what has been already said—else why should it be uttered at all? He is gratified, of course, when this expectation is fulfilled, and would be the reverse if it were not. The latter effect is produced by what is called an anti-climax, the slight shock of the disappointment occasioned by which is sometimes, in suitable circumstances, made available to produce the emotion of the ludicrous. Lord Kames (chap. xviii. § 1) reckons what he calls a *climax in sound* and defines to be the "order of words or members gradually increasing in length," as one of the beauties of language. One example of this which he gives is the following from Cicero: "Quicum quaestor fueram; quicum me sors consuetudoque majorum; quicum me deorum hominumque iudicium conjunxerat." When the climax in sense and the climax in sound coincide in the same passage, he afterwards observes (chap. xviii. § 3), "the concordance of sound and sense is delightful; the reader is conscious not only of pleasure from the two climaxes separately, but of an additional pleasure from their concordance, and from finding the sense so justly imitated by the sound." We may remark that, although an anti-climax, except to produce a ludicrous effect, must always be regarded as a stumble in composition, and is therefore to be avoided, a climax is the favourite ornament of an artificial and mouthy style of rhetoric. A natural writer will commonly come out with the strongest thing he has to say at once, instead of cautiously advancing to it by this sort of measured dance. (For an example of climax from Demosthenes, see 'Demetrius Phal.' *Περὶ Ἑρμηνείας*.)

CLIO. [MUSES.]

CLIPPER. This word has become so thoroughly engrafted on our nautical vocabulary, that it claims some attention. It is used to designate a new construction of vessels, built rather for speed than for their carrying qualities, and seems to have originated principally in the north of England, and also in Scotland, where a spirited ship-builder ventured, a few years since, to leave the trodden path, and enter upon a new field of enterprise, by adding to the mercantile marine specimens of naval architecture which at once met with public approval; and from the increased speed of those vessels, they were styled "Aberdeen Clippers."

Mathematical science has been tortured to produce a knowledge of correct principles as applicable to the water-lines of a ship [NAVAL ARCHITECTURE], and the forms of vessels have undergone changes accordingly. [WAVE PRINCIPLE.] Perhaps few single circumstances have operated more powerfully or more rapidly in producing these changes than the arrival in the Solent of the celebrated yacht called the *America*, in 1851. Her peculiarities were striking. In the first place, all the old seamen's notions of a "good full bow and long floor to catch her in a sea-way," were at once confounded by the plain fact that here was a vessel built with her greatest beam abaft the centre of the ship, which would outsail all our fastest yachts with the greatest ease; and whereas in ordinary vessels they required considerable buoyancy forward to raise them in a sea-way, this, in the American clipper, was effected by the placing of the centre of gravity of the whole mass further aft than usual. And again: a good deep fore-foot had been deemed essential to any vessel intended to have weatherly qualities. In the *America*, however, this was very much diminished, and such weatherly powers were obtained by means of a deepness of keel. And further, the qualification of being quick in stays, which our vague notions had generally attributed to the action and adjustment of the sails alone, was in the *America* secured by her having a very deep heel, so that she drew very considerably more water aft than forward. But that which seemed most to astonish the nautical world was the form of the water-line under the vessel's counter. In the *America*, this water-line altogether may be compared to the shape of the longitudinal section of a pear, the stalk of which might represent the bowsprit. It is even difficult to this day for ordinary sailors to understand the theory of the principle on which her sailing qualities depended.

Those who have been accustomed to combine, in their ideas of necessary form for swiftness, the cod's head and mackerel's tail, saw at once in the *America* those assumed requirements disputed; and even the more thoughtful, remembering the experiments of Colonel Beaufoy (who demonstrated that a taper spar, with truncated ends, required less power to force it through the water with the large end foremost than with the small end), were at a loss to account for the success obtained by the *America*, with such apparently heavy after lines. But a little consideration will remove all doubt; nor need we, in reality, relinquish the good old axioms which attributed speed in vessels to the having a good entry, and the avoidance of dead water. The good entry of the present time, as certainly introduced into England by the *America*, may be said to consist in a considerable lengthening of the proportions of the bow, which throws the heel of the fore-mast further from the fore-foot, and thus eases a vessel in a sea-way. (In some of our coasting schooners and brigs of the old school, the fore-mast seems

almost to step on the fore-foot, and the same defect may be seen in several of our old line-of-battle ships.) With regard to the after-lines, or, as usually called, the run of a ship, such care is taken to prevent her from dragging dead water after her, from faulty deliverance of the fluid displaced, that we have now in our mercantile marine a large number of fast-sailing ships, built professedly with regard to these special qualifications, and to which the term clipper is given by universal consent. But the chief popular error (which still influences many, and is a bar to the full development of greater perfection in the lines of a ship) consists in the taking of the form of the water-surface line only (as many did with the *America*), and pronouncing a run defective or otherwise, according as this line appeared rounded or straight: but it must be remembered, that the progress of a fast-sailing ship, and the consequent displacement of water, creates a sort of imperfect vacuum, into which the fluid from the bends of the ship rushes; and the more nearly straight these lines can be made, the more easily is this vacuum annihilated, and dead water prevented: in other words, the faster the ship will sail. From the above it will be apparent that water may be delivered along the after part of a ship's hull from every possible direction, and speed may therefore be looked for as attainable by not only the sharp deep Ryde wherry, but the flat-bottomed *dish-like* galliot. The former delivers the water horizontally, the latter vertically. The question of mere speed, and the power of being weatherly, are of a totally different nature.

To show that there is room for improvement in some of our most noted ships, the following occurred to the writer of this: One of the fastest of the Liverpool Australian clipper-ships was, two or three years since, in a dry dock. On examination of her lines, a remark escaped him, that she would sail better stern foremost. On her return voyage, it chanced that peculiarity of weather and unavoidable circumstances prolonged her homeward passage to above 100 days. Prompted by curiosity to examine her copper and water-line *when afloat*, the writer, as she lay in the Mersey, had an excellent opportunity, and found that from the stem-piece all along the side of the ship, the copper appeared almost burnished with the friction of the water during so long a continuous and rapid propulsion; but just under the mizen-chains appeared the "plague-spot," where, instead of the brightness seen elsewhere towards the fore-part of the ship, the copper began to show tarnish, until, within a space of certainly not more than six feet, the copper was quite green and corroded,—indisputably indicating a diminution of friction, or a hollowness; and consequently (as further search proved), a serious amount of unnecessary dead water, and hindrance to speed, in this still fine and handsome well-known clipper. Hollow lines forward are said to contribute towards speed, but it is a question if they are admissible abaft.

The word clipper is only applied to vessels engaged in mercantile enterprise, and is not to be confounded with the term yacht. [YACHT.]

CLOACÆ; large arched drains, or sewers, formed under the streets of some ancient Roman cities. The most remarkable were the cloacæ of Rome, large portions of which still remain in excellent repair. These cloacæ are doubtless of high antiquity, and tradition assigns their origin to the time of the first Tarquin. (Livy, i. 38.) According to Livy (v. 55), the chief subterranean passages originally followed the lines of the streets and public places; but in the hurry of rebuilding the city after the Gallic invasion, the old lines of streets were neglected, and the houses were often built across the drains.

The cloacæ of Rome consisted of several branches, which ran in the low part between the hills: these branches fell into one very large arched drain, constructed of solid blocks of stone, called the Cloaca Maxima, said to have been built by Tarquinius Superbus (Livy, i. 56), and repaired, in later times, by Cato the Censor and his colleague in office. A portion of this cloaca is visible near the arch of Janus. It was formerly continued towards the Tiber, passing by the Corinthian peripteral temple, called the Temple of Vesta, close to which it terminated in the Tiber, at a point believed to be the Pulchrum Littus, so called from the sides of the river having a walled embankment with steps. The arched drain of the Cloaca Maxima is fifteen feet wide and thirty high (these dimensions include the masonry), with three arches in contact one within another: in some parts there are raised paths along the sides of the cloaca, and in the walls are stone brackets to support the ends of the waste pipes of the fountains. The three arches are still in excellent order, and exhibit not only a thorough knowledge of the construction of the arch, but admirable workmanship. Niebuhr says that the innermost vault forms a semicircle 18 palms (of 8·79 inches each) in width, and of the same height. This vault is inclosed within a second, and this again within a third. The stone employed, called peperino, is a greenish stone with black specks. The blocks are 7½ palms long and 4½ high. The same writer is of opinion that the Cloaca Maxima was only constructed to drain the Velabrum and the valley of the Circus Maximus. ('Hist. of Rome.') In the year 1742 a part of the Cloaca Maxima was discovered in the Forum, at the depth of thirty feet from the surface, constructed in a similar manner to the part which is seen near the temple of Janus (Nardini, p. 210, lib. v., cap. vii., regio viii.) Niebuhr, on the authority of Ficaroni, says it was constructed of travertino stone, or tufa, and he thinks it of greater antiquity than the peperino construction. Smaller drains of wood or clay intersected the city in every direction, and communicated with the Cloaca Maxima, and drain-pipes or tubes carried off the refuse of

the houses. Until the formation of the sewers of London, there existed no cloacæ or drains for a city which could be compared with the cloacæ of Rome. [SEWERS.]

The maintenance of the Roman cloacæ was originally the business of the censors, but afterwards belonged to the ædiles; Agrippa, during his ædileship, made numerous large cloacæ, of which Pliny (xxxvi. 15) has spoken in terms of unbounded admiration. The emperors created officers called *curatores cloacarum*. The city of Pompeii had cloacæ on a smaller scale, and from the mention made by Diodorus of the cloacæ (*ὀρόνομοι*) of Agrigentum there can be little doubt that other cities were provided with cloacæ, though of course on a much smaller and less complete scale than Rome.

CLOCK AND WATCH-MAKING. There is a close connecting-link, or rather series of links, between the mechanism of a pocket-watch, a chronometer, a spring-clock, and a pendulum-clock, rendering it convenient to treat of them all under one heading. We shall therefore at once refer the reader to the article *HOROLOGY*, for the requisite information on these matters.

CLOISTER, from the Anglo-Saxon *clauȝter* or *clurȝen*, adopted from the Latin *claustrum*, a place inclosed or shut up. The term is more particularly applied to the covered walk or inclosure which was the usual appendage of our ancient monasteries and collegiate establishments, where the inmates met to converse and take exercise, or frequented for the purpose of study. It was also very commonly used as a place of sepulture for the members of the establishment. The cloister was always attached to the church, and was usually carried round the sides of a quadrangle; see the plan of Durham Cathedral in the article *CHURCH*. In a more general sense, cloister is used for a monastery at large, whether of monks or nuns, the inmates being inclosed or shut up from the world. The German word "kloster" retains this original signification.

CLOUD, in meteorology, a mass of aqueous vapour condensed into the visible form, in which it consists of globular particles of water, excessively minute, and probably not vesicular or hollow, the entire congeries of which, when of a certain magnitude and density of aggregation, normally reflects white light, but is translucent and colourless for very small thicknesses, and from its powerful absorptive action upon light in greater but still moderate thicknesses is absolutely opaque. It may float in the atmosphere, or rest on the surface of the earth; but in all cases it is a portion of the aqueous vapour in the atmosphere, separated by reduction of temperature, however effected. When resting on the earth's surface, or produced or existing very near it, that which, when seen above, is termed *cloud*, is familiarly known as *mist* or *fog*; the latter term being also applied to the same object when modified by certain circumstances and additions. The consideration of the mode of production, appearance, disappearance, and results of the clouds, is an important branch of meteorological knowledge, which we shall introduce to our readers by a review of their more obvious phenomena, as made subjects of scientific investigation.

Science is indebted to the veteran meteorologist, Mr. Luke Howard, F.R.S., the author of 'The Climate of London,' and other works, and now (1859) vice-president of the British Meteorological Society, for a classification and nomenclature enabling observers to fix their ideas of the proverbially ever-varying and fleeting forms presented by the condensed vapours of the atmosphere, which, after the experience of more than half a century, in the hands of men of science, meteorologists and physicists, of every country and of every grade, has been found universally applicable, in all climates, and in all general or local conditions of the atmosphere, and has scarcely been found susceptible either of change or of addition. This classification and nomenclature was first enunciated in an essay read by Mr. Howard before the Askesian Society (already noticed in this *Cyclopædia*, *BIOG. DIV.*, *PEPYS*, *WILLIAM HASLEDINE*; *PHILLIPS*, *RICHARD*; and *PHILLIPS*, *WILLIAM*), in the session 1802-1803, and originally published in the 'Philosophical Magazine,' first series, vols. xvi. xvii., 1803, 1804, in the form of a paper, containing the substance of that essay, 'On the Modifications of clouds, and on the Principles of their Production, Suspension, and Destruction.' It was reproduced, with some changes not affecting the nomenclature, in Rees's '*Cyclopædia*,' in the article 'Cloud,' of which Mr. Howard was the author; and this was reprinted by William Nicholson, in his well-known 'Journal of Natural Philosophy,' &c., 8vo series, for September, 1811, vol. xxx., p. 35-62.

At the end of the second volume of his work on the 'Climate of London,' published in 1820, Mr. Howard gave the 'Terminology of Clouds,' &c., as an extract from his paper; and in the second edition of that work, published in 1833, he republished the paper itself, which, with some notes, forms a portion of the introductory matter to the first volume, having also been separately printed and published in the preceding year. From this is derived the following view of the subject.

Mr. Howard applies "to the various forms of suspended water" the term "modifications of cloud;" and after stating that "there are three simple and distinct modifications, in any one of which the aggregate of minute drops, called a cloud, may be formed, increase to its greatest extent, and finally decrease and disappear," he proceeds to describe substantially in the following terms, first the simple, and then the intermediate and compound modifications, prefacing the description

of each by its definition. To the characters of the first three modifications, some particulars derived from Sir John F. W. Herschel, are here added. The primary modifications are thus defined and described:—

Cirrus. Parallel, flexuous, or diverging fibres, extensible by increase in any or all directions. They are the earliest appearance after serene weather, being first indicated by a few threads pencilled as it were on the sky. These increase in length, and new ones are at the same time added to them. The first formed threads serve as stems to support numerous branches, which in their turn give rise to others. The upward direction of the fibres or tufts of this cloud has been found to be a decided indication of the condensation of the aqueous vapour in the air preceding rain; their downward direction indicates evaporation and fair weather. The cirrus, of all the modifications of cloud, has the least density of aggregation, the greatest elevation, and the greatest variety of extent and direction.

The name of *mare's-tails*, by which cirri are commonly known, describes their aspect well. Their filamentous structure clearly indicates them as in the act of originating from the production of visible vapour from the union of aerial currents of different temperatures running parallel to each other. From their great elevation it is more than probable that their particles are frozen, and of course crystalline, and that to this constitution it is owing that halos, coronæ, and other optical appearances, referable (as originally inferred, we believe, by Dr. T. Young) to reflections and refractions in ice-crystals, appear almost invariably in cirrus and in its derivative forms, especially the cirro-stratus. Cirrus is said to be often a precursor of windy weather. Some interesting, but at present obscure, relations between this modification of cloud and the *POLAR LIGHTS* will be alluded to in the article on that subject.

Cumulus. Convex or conical heaps, increasing upward from a horizontal base. Clouds in this modification are commonly of the most dense texture; they are generally formed in the lower nubiferous atmosphere, and move along with the current which is next the earth. A small irregular spot first appears, and is, as it were, the nucleus on which the increase takes place. The lower surface continues irregularly plane, while the upper rises into conical or hemispherical heaps, which may afterwards continue long nearly of the same bulk, or rapidly grow to the size of mountains. [Prof. James Forbes observed from the summit of the Jungfrau, in the Bernese Alps, a single "magnificent cumulus-headed cloud," reaching apparently from the valley below to at least 2000 feet above the mountain, so that its vertical thickness or height must have been at least 10,000 feet, or about two miles.] In the former case cumuli are usually numerous and near together, in the latter comparatively few and distant; but whether there are few or many, their bases lie nearly in one horizontal plane, and their increase upward is somewhat proportionate to the extent of base. The cumulus of fair weather has a moderate elevation and extent, and a well-defined rounded surface. Previous to rain it increases more rapidly, appears lower in the atmosphere, and with its surface full of loose fleeces or protuberances, it being now *efflorescent*, as it were, on the great scale.

A particular account of the production of this modification, by Sir John Herschel, will be found in the general views of the formation and nature of clouds given in the sequel of this article.

Stratus. A widely extended, continuous, horizontal sheet, increasing from below upward. It is of intermediate density of aggregation, but is the lowest of clouds, its inferior surface commonly resting on the earth or on water. Contrary to the cumulus, which may be considered as belonging to the *day*, this is properly the cloud of *night*; the time of its first appearance being about sunset. It comprehends all those creeping mists which in calm evenings ascend in spreading sheets (like an inundation) from the bottom of valleys and the surface of lakes, rivers, and other pieces of water, to cover the surrounding country. Its duration is frequently through the night. On the return of the sun the level surface of this cloud begins to put on the appearance of cumulus, the whole at the same time separating from the ground. The continuity is next destroyed, and the cloud ascends and evaporates, or passes off with the morning breeze. This change has been long experienced as a prognostic of fair weather, and indeed there is none more serene than that which is ushered in by it.

When the dew-point is attained at some definite altitude above the ground, stratus is also formed there; of which Sir J. Herschel records an instance in which the cloud was extended in the air at the rate of 300 miles in an hour, in the direction of the depression of temperature caused by the setting of the sun.

The two intermediate modifications are:—

Cirro-cumulus. Small, well-defined, roundish masses, in close horizontal arrangement or contact. The cirrus having continued for some time increasing or stationary, usually passes either into the cirro-cumulus or the cirro-stratus, at the same time descending to a lower station in the atmosphere. It is formed from a cirrus, or from a number of small separate cirri, by the fibres collapsing as it were, and passing into small roundish masses, in which the texture of the cirrus is no longer discernible, although they still retain somewhat of the same relative arrangement. This modification forms a very beautiful sky, sometimes exhibiting numerous distinct beds of these small connected clouds, floating at different altitudes. It is frequent

in summer, and is attendant on warm and dry weather. It may either evaporate or gradually become cirrus or cirro-stratus.

Cirro-stratus. Horizontal or slightly inclined masses, attenuated towards a part or the whole of their circumference, bent downward, or undulated; separate, or in groups consisting of small clouds having these characters. This cloud appears to result from the subsidence of the fibres of the cirrus to a horizontal position, at the same time that they approach towards each other laterally. The form and relative position, when seen in the distance, frequently give the idea of shoals of fish. Yet in this, as in other instances, the structure must be attended to rather than the form, which varies much, presenting at times the appearance of parallel bars, or interwoven streaks like the grain of polished wood. It is thick in the middle and attenuated towards the edge. The cirro-stratus precedes wind and rain, the near or distant approach of which may sometimes be estimated from its greater or less abundance and permanence; it is almost always to be seen in the intervals of storms. Sometimes this and the cirro-cumulus appear together in the sky, and even alternate with each other in the same cloud, when the different evolutions which take place are a curious spectacle, and a judgment may be formed of the weather likely to ensue by observing which modification prevails at last. The cirro-stratus is also, as indicated under *Cirrus*, the modification which most frequently and completely exhibits the phenomena of the solar and lunar halo, and also the parheliion and paraselene. Hence the reason of the prognostic of foul weather commonly drawn from the appearance of halo.

The compound modifications are:—

Cumulo-stratus. The cirro-stratus blended with the cumulus, and either appearing intermixed with the heaps of the latter, or superadding a wide-spread structure to its base. "This," remarks Sir J. Herschel, "would seem to be the modification of *cumulus*, when the columns of rising vapour which go to form it arrive in an upper atmosphere not sufficiently dry to round off its summits by rapid evaporation, allowing them to spread horizontally and form flat-topped, mushroom-shaped masses; the upper parts of which are often curled by the wind of an upper current into cirrous wisps, or cleanly cut off by a horizontal plane, forming an 'anvil-shaped cloud,' with a lateral projection, generally considered as a precursor of wind below. Its tendency is to spread, overcast the sky, and settle down into the *nimbus*," which finally falls in rain.

"When," according to Mr. Howard, "a whole sky is crowded with this modification, the appearances are indistinct. The cumulus rises through the interstices of the superior clouds; and the whole, seen as it passes off in the distant horizon, presents to the fancy mountains covered with snow, intersected with darker ridges, lakes of water, rocks, and towers, &c. The *distinct* cumulo-stratus is formed in the interval between the first appearance of the fleecy cumulus and the commencement of rain, while the lower atmosphere is yet dry; also during the approach of thunder-storms; the *indistinct* appearance of it is chiefly in the longer or shorter intervals of showers of rain, snow, or hail."

Nimbus, or Cumulo-cirro-stratus. The rain-cloud. A cloud, or system of clouds, from which rain is falling. It is a horizontal sheet, above which the cirrus spreads, while the cumulus enters it laterally and from beneath. It is the lowest of clouds next to the stratus. Clouds in any one of the preceding modifications, at the same degree of elevation, or in two or more of them at different elevations, may increase so as completely to obscure the sky; and may at times put on an appearance of density, which to the inexperienced observer indicates the speedy commencement of rain. "It is nevertheless extremely probable," Mr. Howard states, "as well from attentive observation as from a consideration of the several modes of their production, that clouds, while in any of these states, do not at any time let fall rain. Before this effect takes place, they have been uniformly found to undergo a change attended with appearances sufficiently remarkable to constitute a distinct modification. These appearances, when the rain happens overhead, are but imperfectly seen. We can then only observe, before the arrival of the denser and lower clouds, or through their interstices, that there exists at a greater altitude a thin light veil, or at least a hazy turbidness. When this has considerably increased, we see the lower clouds spread themselves till they unite in all points and form one uniform sheet. The rain then commences; and the lower clouds, arriving from the windward, move under this sheet, and are successively lost in it. When the latter cease to arrive, or when the sheet breaks (letting through the sunbeams), every one's experience teaches him to expect an abatement or cessation of the rain. But there often follows, what seems hitherto to have been unnoticed, an immediate and great addition to the quantity of cloud. At the same time the actual obscurity is lessened, because the arrangement which now returns, gives freer passage to the rays of light; for on the cessation of rain, the lower broken clouds which remain rise into cumuli, and the superior sheet puts on the various forms of the cirro-stratus, sometimes passing to the cirro-cumulus. . . . The nimbus, although in itself one of the least beautiful clouds, is yet now and then superbly decorated with its attendant the rainbow: which is seen in perfection when backed by the widely extended uniform gloom of this modification."

Further particulars of all the modifications of cloud, and their connection with the weather, and with other atmospheric phenomena, will be found in Mr. Howard's work. In the 'Meteorological Observations'

made at the Royal Observatory, and annually published in the 'Greenwich Observations,'—as stated in the 'Introduction,'—"the clouds and weather are described generally by Howard's Nomenclature;" the following notation being used for the former: *ci. cirrus*, *ci-cu. cirro-cumulus*, *ci-s. cirro-stratus*, *cu. cumulus*, *cu-s. cumulo-stratus*, *n. nimbus*, *s. stratus*. The only adjectives, we may add, which have been formed from these names are "cirrose" and "cirrous," identical in signification, of which the latter is generally employed.

Rear-Admiral Robert Fitz Roy, F.R.S., now Superintendent of the Meteorological Department of the Board of Trade, in London, in his Appendix (published in 1839) to vol. ii. of the 'Narrative of the Surveying Voyages of H.M.S. Adventure and Beagle,' the latter of which he commanded, and in which, besides examining the southern shores of South America, he circumnavigated the globe, has given, pp. 275-6, and illustrated in four plates, a modified classification and nomenclature of the Clouds, in which he has in one direction contracted those of Mr. Howard, and in another greatly extended them. Substituting the term "class" for "modification," he divides clouds into four classes, "cirrus, stratus, nimbus, cumulus;" thus regarding the nimbus, which Mr. Howard considers to be compounded of the other three, as of equal rank in the classification with each of them—as it were as a simple modification. Adopting Mr. Howard's terms for the intermediate and compound modifications (but, with a want of precision often observable in those meteorologists who have in a general manner followed him, ascribing to the former the character of being mixtures of simple modifications, which is true only of the latter), Admiral Fitzroy adds, "Which terms may be rendered more explanatory of the precise kind of cloud by using the augmentative termination *onus*, or the diminutive, *itus*. Thus: *cirronus*, *cirritus*; *cirrono-stratus*, *cirrito-stratus*; *cirrono-cumulus*, *cirrito-cumulus*; *stratonus*, *stratitus*; *cumulonus*, *cumulitus*; *cumulono-stratus*, *cumulito-stratus*. Should these be found insufficient," he continues, "to convey distinct ideas of every variety of clouds, the second word may be augmented or diminished thus: *cirrono-stratitus*," &c. He also partially adopts an English nomenclature for his classes of cloud, which had first been proposed some years after the publication of Mr. Howard's paper; thus: *curl-cloud*, *flat-cloud*, *rain-cloud*, *heap-cloud*. But, as Mr. Howard had remarked ('Clim. of Lond.' first edit. vol. i. p. xxxii.) the English words employed do not fully denote the ideas expressed by the Latin terms he had given, which have the further advantage of being adapted for use in all countries. And accordingly, although half a century has elapsed since the first suggestion of the English terms, and twenty years since its revival by Admiral Fitz Roy, meteorologists and other observers have continued to employ Mr. Howard's original designations.

It may be doubted, also, whether the extended nomenclature in Latin proposed by Admiral Fitz Roy, would not, if adopted, become rather an incumbrance than a benefit. Frequent observation of the clouds for a considerable period,—and for several years under the personal correction of the author of the original nomenclature himself,—appears to the present writer to justify him in the opinion, that if the additional denominations are to be regarded as expressing only the increased or diminished magnitude of the several modifications as witnessed, they are unnecessary, it being better to use ordinary descriptive language for the purpose; and that, if they be regarded as describing minute variations in the aspect of the clouds, they involve an attempt minutely to define that which is too irregular and uncertain to be made the subject of formal science. The examination of the figures given in the plates confirms this opinion; but it may be admitted on the other hand, that Admiral Fitz Roy has observed the clouds over a greater area of the globe, in longitude and latitude, than most other meteorologists who have attended to them, and that an objection similar to the last has been made at various periods to Mr. Howard's classification itself. The sufficiency of this, however, appears to have been established by the judgment of meteorologists in general, the only one who has even partially adopted the extension of it, as far as we are aware, being Professor C. Piazzzi Smyth, and he, in his two works on the Teneriffe Astronomical Experiment, has merely added the augmented term *cumuloni* to Mr. Howard's original designations; while he is known to have recorded his experience of their equal applicability, also, in climes so different and so distant from Teneriffe, as well as from each other, as South Africa and Great Britain.

Sir J. F. W. Herschel, whose observations of the heavenly bodies have led him to give constant attention to the processes going on in the medium through which they are necessarily viewed, has recorded in his memoirs of special astronomical or other observations, and philosophically considered in his more general treatises, many of the more important phenomena of the clouds, which he has treated in a very original manner, evolving, we believe, some comprehensive truths, for which we are either entirely or principally indebted to him. Thus he shows, in the article 'Meteorology,' in the eighth edition of the 'Encyclopædia Britannica' (from which also are derived the additional characters of certain modifications already given), that when a body of vapour is generated from any warm evaporating surface, it ascends by its relative levity, losing sensible heat, as well by its own expansion as by its bodily transfer into and intermixture with colder air. Should the supply of vapour, however, not be very copious, and should it find itself in its ascent always in a region hygrometrically dry, it by no means follows that it will reach the point of precipitation; but should

the reverse of these conditions obtain, namely, a copious and continual supply from below, and a state of vaporous tension already existing aloft approaching saturation, a portion will be precipitated in visible cloud, on arriving at a certain level. When this process takes place in a calm state of the air, and the evaporating surface is limited in extent, or irregularly distributed in patches (as over marshy ground, rivers, lakes, &c.), or if any other cause dispose the vapour to rise in columnar bodies of greater or less extent, the summits of these are marked by protuberant masses, or piles of cloud, with generally rounded outlines, which appear to repose on flat bases, indicating the "vapour plane," [VAPOUR-PLANE] or that level where hygrometric saturation commences. These are cumuli. So produced, "they abound," Sir J. Herschel observes, "in the calm latitudes of the equatorial seas, and form a distinguishing feature in the meteorology of that region."

"That the mere self-expansion of the ascending air," he continues, "is sufficient to cause precipitation of some of its vapour, when abundant, is rendered matter of ocular demonstration in that very striking phenomenon so common at the Cape of Good Hope, where the south or south-westerly wind which sweeps over the Southern Ocean, impinging on the long range of rocks which terminates in the Table Mountain, is thrown up by them, makes a clear sweep over the flat table-land which forms the summit of that mountain (about 3850 feet high), and thence plunges down with the violence of a cataract, clinging close to the mural precipices that form a kind of background to Cape Town, which it fills with dust and uproar. A perfectly cloudless sky meanwhile prevails over the town, the sea, and the level country; but the mountain is covered with a dense white cloud, reaching to no great height above its summit, and quite level, which, though evidently swept along by the wind, and hurried furiously over the edge of the precipice, dissolves and completely disappears on a definite level, suggesting the idea (whence it derives its name) of a 'Table-cloth.' Occasionally, when the wind is very violent, a ripple is formed in the aerial current, which, by a sort of rebound in the hollow of the amphitheatre in which Cape Town stands, is again thrown up, just over the edge of the sea, vertically over the jetty, where we have stood for hours watching a small white patch of cloud in the zenith, a few acres in extent, in violent internal agitation (from the hurricane of wind blowing through it), yet immovable, as if fixed by some spell, the material ever changing, the form and aspect unvarying."

Of the suspension of the clouds in the air, a subject apparently very simple, but which really involves a variety of physical principles, the most recent view is that of Sir J. Herschel also, stated in the following terms, in the article already cited:—

"When the sun shines on a cloud which absorbs its heat, the cloud itself is necessarily partially evaporated, and the vapour, by its levity, tends to produce an upward current, and thus to counteract the effect of gravity on the globules of which it consists. A globule of water $\frac{1}{4000}$ in. in diameter, in air of five-sixths of the density on the surface, or at the height of about 5000 feet, would have its gravity counteracted by resistance, with a velocity of descent of one foot per second (supposing no friction and no drag); and even if the terminal velocity were reduced to half that quantity by these causes, would still require some such upward action to enable it to maintain its level—a circumstance which sufficiently accounts for the lower level generally observed of cloud during the night. It is more than probable, however, that when not actually raining, cloud is always in process of generation from below and dissolution from above, and that the moment this process ceases, rain in the form of 'mizzle' commences. In a word, a cloud, in general, would seem to be merely the visible form of an aerial space in which certain processes are at the moment *in equilibrio*, and all the particles in a state of upward movement."

Just pausing to call attention to the important inference with respect to the abstract nature of a cloud, first drawn, we believe, by the accomplished philosopher we are quoting, and contained in the last period of this extract,—we may observe that, to complete the view he takes of the causes of the suspension of the clouds, nothing seems to be required but an adequate estimate of the effects of the 'friction' and the 'drag,' which are supposed not to exist. But it appears to have escaped the attention of Sir J. Herschel, that Professor G. G. Stokes had already shown that the internal friction of the air, together, of course, by implication, with the drag which it occasions, is itself one of the causes—in his opinion, indeed, the main cause—of the suspension of the clouds. As this particular subject is new, and of great importance in meteorology, we shall treat it at some comparative length.

Clouds consist of an aggregation of separate minute globules of water; and the resistance of such a globule falling through the air with its terminal velocity depends almost wholly on the cause just stated. "Since the index of friction of air is known from pendulum experiments, we may," Professor Stokes observes, "easily calculate the terminal velocity of a globule of given size, neglecting the part of the resistance which depends upon the square of the velocity. The terminal velocity thus obtained is so small in the case of small globules, such as those of which we may conceive a cloud to be composed, that the apparent suspension of the clouds does not seem to present any difficulty. . . . Since in the case of minute globules falling with their terminal velocity the part of the resistance depending upon the

square of the velocity is quite insignificant (as will presently be shown) compared with the part which depends on the external friction of the air, it follows that were the pressure equal in all directions in air in the state of motion (which according to the common theory of the fundamental assumption in hydrodynamics, it would be), the quantity of water which would remain suspended in the state of cloud would be enormously diminished.

To render this view of the subject complete, and to explain the value of the last observation, it must here be stated that Professor Stokes had before shown that the fundamental assumption of hydrostatics and hydrodynamics, that the pressure of a fluid is equal in all directions, though fully justified by experiment in the case of a fluid at rest, is not true in the case of a fluid in motion. The viscosity attributed to water by Dubuat, and the inherent property, "analogous to that of viscosity in liquids," ascribed to elastic fluids by Captain (now Major-General) Sabine, from their respective pendulum experiments, were generalised by Professor Stokes as consequences of the internal friction of fluids in general, all fluids exerting a resistance to bodies passing through them, independently of their density; and when this is taken into account, it is evident that the pressure cannot be equal in all directions.

The suspension of the globules of water forming the clouds is only a particular case of the more general fact, that fine powders remain nearly suspended in a fluid of widely different specific gravity. Professor Stokes has demonstrated that the resistance of the fluid, whether liquid or gaseous, is proportional, not to the surface, but to the radius of the spherule, and consequently the quotient of the resistance divided by the mass,—in other words, the accelerating force of the resistance,—increases much more rapidly as the radius diminishes, than if the resistance varied as the surface: on which principle the suspension, or proximate suspension, of the particles or globules depends. When the downward motion of a globule is so slow that the part of the resistance which depends on the square of the velocity may be neglected, the terminal velocity of a globule of water forming part of a cloud may be determined. For a globule the one-thousandth of an inch in diameter, we have the velocity 1.593 inch per second. For a globule the one ten-thousandth of an inch in diameter, the terminal velocity would be a hundred times smaller, so as not to amount to the one sixtieth part of an inch per second.

The amount of that part of the resistance which varies as the square of the velocity, is the only kind of resistance that could exist if the pressure were equal in all directions, for the velocity 1.593 inch per second is not quite the one four-hundredth part of the weight; and for a sphere only the one ten-thousandth of an inch in diameter, the ratio of the resistance to the weight would be ten times as small. Both these proportions, it is manifest, are quite insignificant.

The conclusion thus arrived at by Professor Stokes as to the cause of the suspension of the clouds, illustrates in a remarkable manner the connection of different branches of science. It is an application by him of the theory of internal friction, as applied to the ball pendulum, and verified by recorded experiments on that instrument, and is contained in his memoir 'On the Effect of the Internal Friction of Fluids on the Motion of Pendulums,' published in the 'Transactions of the Cambridge Philosophical Society,' vol. ix. The erroneous extension of the fundamental law of hydrostatics had been discussed by him in a paper 'On some Cases of Fluid Motion,' inserted in the preceding volume of that work.

The height of the clouds in the atmosphere at any particular locality necessarily varies, like their production itself, with the quantity of vapour in the air, the climate, the season, the temperature at the time of observation, the local decrement of temperature for ascent, the elevation of the superimposed currents of air, the extent of the land, the proximity of the sea, the existence and altitude of mountains, and a variety of other circumstances relating both to the earth and the atmosphere. It would appear that the altitude of the highest mountains gives the upper limit of the region of the clouds, which is thus seen to comprise those denser strata of the atmosphere resting immediately on the earth's surface, which include considerably more than two-thirds of the ponderable body of air incumbent on the globe, the highest mountains known not exceeding five miles and a-half in height; while the principal mass of the clouds probably belongs to a region of which the superior limit is about a mile below this. Mr. Dalton correctly asserted, that in England the height of small fleecy patches of cloud, meaning *cirri*, was frequently from three to five miles. The following observations, relating to the elevation of the clouds in the interesting district of the English lake mountains, are given by Mr. Dalton in the first edition of his 'Meteorological Essays' (1793), the observer being Mr. Crosthwaite of Keswick. By accurate measurement of Skiddaw, and fixing marks on the side of the mountain, which is 1050 yards high [correctly 1007 yards], he was able to ascertain by inspection the height of any cloud, when it did not exceed that of the mountain.

This he did three times each day, morning, noon, and evening, for five years, missing only as many observations as amounted to omitting less than a week per year. The result is as follows, the last column but one giving the number of times in which either the clouds were above the mountain, or there were no clouds at all, the last circumstance occurring about once out of thirty times.

Thus, it appears that in the month of September, for instance, for seven times that the clouds were between 200 and 300 yards high, there were 38 times in which they were between 500 and 600 yards high, &c. The supposition of the height of the clouds depending on the barometer, was in no degree countenanced, and though in heavy and continued rains the clouds were mostly below the summit, yet it frequently rained when they were above it. These observations, however, are chiefly valuable in relation to the local phenomena. (See J. F. Miller on the Meteorology of the Lake District, in 'Phil. Trans.,' 1848, p. 87.) Of much greater importance are those of the late Mr. John Welsh, F.R.S., in four balloon ascents, made in 1852, under the direction of the Kew Observatory committee of the British Association for the Advancement of Science, and published in 'Phil. Trans.,' 1853. The ascents were all made from Vauxhall Gardens, on the south bank of the river Thames, in the south-west district of London.

At the first ascent, on August 17th, 1852, clouds covered about three-fourths of the sky, the lowest stratum being a few detached masses of loose cumulus; a dense mass of cirro-stratus (or stratus) being above, with perhaps occasional patches of cumulus intermediate. The altitude of the lowest clouds, which extended only over a small area, was estimated during the ascent at about 2500 feet, or 500 feet less than that of Skiddaw. Between this and about 13,000 feet, the air seemed free of clouds; after this, there seemed to be occasional masses of loose cumulus at no great distance. When at the greatest elevation, 19,510 feet, or about three miles and three-quarters, there was, at apparently a short distance above the balloon, a thick mass of cloud, probably the cirro-stratus which had been seen from the earth. At this elevation the temperature was 9.5°, or 22.5° below freezing; and at about this time, though while still rising, a few small star-shaped crystals of snow fell, a fact coincident with what has been remarked in a former part of this article, of the probably frozen condition of cirrus. At the second ascent, on the 26th of August, the sky was to a small extent obscured by detached masses of cumulus, but the sun shone brightly throughout the ascent. The only clouds passed were at the estimated height of 3000 feet; above this no clouds were met with, while the ascent was made to 19,100 feet, the sky being exceedingly clear, and of a very deep blue colour. The third ascent was made on October 21st, on the morning of which a fog which had existed on the previous night slowly disappeared, leaving the air in a very calm state and with some haze. A dense mass of cloud, probably stratus, covered the sky; one or two slight showers falling about 10 A.M. Between the heights of 1000 and 2800 feet various detached and irregular masses of loose "scud" were encountered, but the balloon had not completely entered the dense mass of cloud till the height of nearly 3000 feet. At a height of 3700 feet the upper surface of the cloud was reached, and the sun was seen shining through thin cirrous clouds at a great height. The height of the upper surface of the cloud was again observed during the descent to be 3450 feet. When the balloon was close to the clouds, it was remarked that the general level of the surface was very uniform, presenting however a hillocky appearance; the irregularities being small, apparently not exceeding a very few feet. Shortly after clearing the clouds, a shadow of the balloon was seen on the surface, fringed with a glory; with this shadow as a centre, there was also observed a circle of whitish light, the outer edge of it slightly tinged with yellow; its diameter being estimated at 80°. About this time there was noticed, stretching for a considerable length in a serpentine course over the surface of the cloud, a well-defined belt, having the appearance of a broad road, both sides being strikingly distinct. The thin cirrous clouds already mentioned seem not to have been passed, the descent being made from the elevation of 12,640 feet, at which the temperature was 26.7°.

The reader will not fail to connect the thin cirrous clouds seen at a great height, through which the sun was shining, with the glory and the circle of light surrounding the shadow, and remark in reference to the

frozen state of such clouds both the fact that they were above 12,000 feet, and the temperature observed. Perhaps the serpentine belt may have been the horizontal summit or upper plane of a comparatively narrow current of air with vertical sides, which had deposited its own mass of cloud, in the form of a waved wall.

The fourth and last ascent took place on the 10th of November, when the surface wind and the lower current of "scud" were moving very slowly; the upper clouds were only occasionally visible. At a height of 500 feet the first cloud, thin scud, was entered, the upper surface being 1970 feet high. A space of 2000 feet was clear of clouds, and at 4000 feet the second stratum of clouds was reached, its upper surface being found to be 4900 feet high. After this no clouds were met with, the sun shining through thin cirrous clouds, which must have been at a very great height. The greatest elevation attained was 22,930 feet, and the lowest temperature observed, at 560 feet lower, was 10.5° below zero. So that the height of the cirrus was above 23,000 feet, or about four miles and three-eighths, at which it must necessarily have been frozen, to have a visible existence in clear sunshine; and the same inference may in fact be drawn with respect to some of the preceding instances at much lower altitudes.

The nautical term *scud*, denoting, apparently, broken fragments of cloud, is frequently employed by meteorologists at the present time, as by Mr. Welsh above, and in the Greenwich observations; but we must confess our ignorance to what modification and in what state it is intended to apply, or whether it is regarded as equivalent to an additional modification: an ignorance in which we know Mr. Howard to participate. Its undefined use seems to indicate insufficient attention to the structure of the clouds.

Of the elevation and distribution of the clouds at Teneriffe, we have some definite information in Professor C. Piazzi Smyth's report (already cited) of the astronomical experiment of 1856 made on the Peak (or in 'Phil. Trans.,' 1858), pp. 481, 527. Observed both from the upper station of Alta Vista at the height of 10,702 feet above the sea, and the lower one of Guajara at that of 8,903 feet—though fog and mountain-cloud existed below and appeared daily, dense, closely packed together, and rolling upon each other—they showed no tendency to rise higher than 4500 feet, or rather more than seven-eighths of a mile. With this depression of the mountain-cloud, including cumulus, cumulo-stratus, and nimbus, below him, Professor Smyth had, he found, but the thinner forms of cloud, cirrus, cirro-cumulus, and some cirro-stratus, ever at any time floating above him, or interfering with the view of the heavens; and these only appeared about once in five days in any considerable quantity. The lowest strata of cloud, he observed, were 2300 feet, or less than half a mile, above the sea; of the elevation of the upper clouds he had no means of accurately judging, but he suspected that it could not have been less than 15,000 feet, or nearly three miles. Sometimes there was cloud on the summit of the Peak, which gives a height of 12,000 feet, about two miles and a-quarter. Professor Smyth also observed that the stratum of the mountain-cloud of Teneriffe did not occur in the space between the two winds which were found blowing at the top and bottom of the mountain, respectively, the S.W. wind above and the N.E. trade-wind below [CALM], but in or below the middle of the N.E. current of air, which extends in height from the very sea itself to about 9000 feet. The mountain-cloud is limited in horizontal extent to a few miles, but even the sea-cloud, the true N.E. cloud, which was far more extensive, stretching as far as the eye could observe, when viewed from many thousand feet above, and extending, in fact, several hundred miles from the island, only reached to between 4000 and 5000 feet of elevation, or to half the height or depth of the N.E. wind, in the midst of which, like the mountain-cloud, it was thus included. It seems probable, therefore, that in all climates, the rainless tracts excepted, a considerable stratum of cloud commonly exists over the land, the inferior surface of which is at a height varying from somewhat less to rather more than half a mile, or from 2500 to 3000 feet, whatever of cloud there may or may not exist above or below that altitude. CLOVER, a name given to different species of *Trifolium*. Dutch clover is *T. repens*; purple clover is *T. pratense*; cow-grass, or perennial clover is *T. pratense perenne*; Alsike clover is *T. hybridum*; *T. medium* is also called cow-grass; scarlet clover *T. incarnatum*; hop trefoil is *T. procumbens*.

Clover was introduced into the agriculture of Great Britain about the 16th century, from the Low Countries, where it had been long cultivated as green food for cattle in situations where natural pastures were scarce. It was the first step towards the improvement of the old triennial system. Its abundant produce, its destruction of annual weeds, which it smothers by its broad foliage, and especially the beauty of the wheat sown after it, soon recommended it as an indispensable part of an improved rotation of crops. It is not too much to say, that under certain kinds of management, the profit of any farm may be considered as proportionate to the quantity of clover which is produced upon it on an average of years. There are various kinds of clover, which all go under the botanical name of *trifolium*, from the three leaves which grow together, or rather the form of the leaf, which has three heart-shaped parts. They are annual, biennial, or perennial plants. The annual clovers, with the exception of the *trifolium incarnatum* (*Trèfle incarnat* or *farouche*), introduced from the south of

France, are not so generally cultivated as the biennial, which produces a greater crop, and being sown along with the spring corn comes up the first year under its shade, and gives a full crop in the second. In good land it will sometimes stand another year, but it falls off in quantity; and unless other artificial grasses or perennial clovers have been sown amongst it, to fill up the places where the biennial clover has failed, it is seldom profitable to allow it to remain on the ground more than one year after that in which it is sown.

The most approved variety of the biennial clovers is the common red or broad clover (*Trifolium pratense*), which is usually sown with barley or oats, or sometimes among wheat or rye in spring. When these are drilled and hoed there is an advantage in sowing the clover seed among a crop which is already advanced in growth, because it is kept under, and there is no danger of its injuring the chief crop by its too great luxuriance. There is however some risk of the clover not coming up so well, if the wheat or rye is very close on the ground. In Scotland clover is often sown among wheat, in Norfolk invariably with barley, and in Belgium among rye. This depends on the various rotations adopted in different countries. The first crop is generally mown and made into hay. In this process great care is taken not to break off the tender leaves of the plant in drying; the swathe is not shaken out as is done with meadow grass, but merely turned over; and if the clover can be dried and put in a stack without any shaking, it is so much the more valuable. When clover is soaked with rain, no hope of an improvement in the stack must induce the farmer to carry it together, so long as the least moisture remains. If it is allowed to stay in the field till it is perfectly dry, even when it has been soaked repeatedly and is nearly black, and is then trod hard in a rick with a sprinkling of salt over each layer, it will be readily eaten by cattle in winter, and be far more nutritious than that which, having been stacked in a moist state, will infallibly come out musty. A very good method in those seasons when a continuance of dry weather cannot be reckoned upon—particularly when the second crop is cut in September—is to take advantage of two or three dry days to cut the clover, and turn it as soon as the dew is completely dried off the upper side; the next day do the same, and in the evening carry the green dry clover and lay it in alternate layers with sweet straw, so as to form a moderately sized stack. A fermentation will soon arise, but the dry straw will prevent all danger from too much heating, and, acquiring the flavour of the clover, will be eaten with avidity by the cattle. To those who make clover-hay for the use of their own stock in winter, we recommend this as preferable to the common method, even when there is less danger from the weather. In northern climates it would probably save the crop two years out of three.

It is usual to sow rye-grass (*Lolium perenne*) in a small proportion with clover seed, especially where clover, having been often repeated on the same land, is apt to fail. It is a good practice; and although in the neighbourhood of London the unmixed clover obtains a better price, there is no reason why it should be preferred, unless the rye-grass has been allowed to stand too long and has grown hard. Young rye-grass is a good corrective of the heating qualities of clover-hay. A very extensive use of clover-hay in London is to cut it into chaff, and to mix with oats and beans for dray horses, which have little or no hay given them in any other way; but the most profitable use of clover is to cut it green for horses and cattle. With a little management and the assistance of tares, green food may be given to all the stock from the first day of May to the end of November.

The land which has borne clover, although in a very good state for producing corn, will not bear a repetition of that crop until several other crops have intervened. In the regular Norfolk rotation, clover should recur every fourth year; but after a few rotations this is found to be too quick a recurrence, and other grass seeds or pulse are substituted.

The white or Dutch clover (*Trifolium repens*) is a perennial, which grows rapidly, and forms excellent pasture; but its bulk is not sufficient to make it profitable to mow it for hay. It is excellent for sheep, which thrive well upon it. A light calcareous soil is best adapted for white clover; but it also grows well on heavy land, provided the bottom be sound and dry. When land is laid down for permanent pasture, white clover is always sown in considerable proportion with other grasses.

Another perennial clover, called cow grass (*Trifolium medium*), is found in all rich meadows. It is often sown in conjunction with the white clover, in laying down arable land to grass. The lesser yellow trefoil (*Trifolium minus*), and the hop trefoil (*Trifolium procumbens*), are also valuable varieties found in good pastures.

The only annual clover which is cultivated is the French clover (*Trifolium incarnatum*), mentioned before. It is a most valuable addition to the plants usually sown for fodder, from the short time in which it arrives at perfection, if sown in spring; so that where clover has failed, this may be sown to fill up the bare places. Its principal use is to raise very early food for ewes and lambs, which it does with very little trouble or expense. Immediately after harvest, the stubble is scarified and harrowed so as to raise a mould; the *Trifolium* is sown at the rate of 16 to 20 lbs. per acre, and well rolled in. It springs up and stands the winter well, and with the first genial weather in spring it grows rapidly. It makes a coarse but tolerable hay, and what is left produces seed most abundantly in the beginning of June, being off the ground in good time to plough the land and clean it for turnips.

It is far superior to stubble turnips as an intervening crop, and more rapid in its growth than tares. On light land a crop of turnips is readily obtained after it. It has the property of smothering annual weeds by its rapid growth, and for this reason is not so well adapted for sowing with a crop of corn. The Italian rye-grass (*Lolium perenne Italicum*) may be sown with it, and will grow as rapidly. After the *Trifolium* has been cut, this will continue and give an excellent second crop. It is advisable to have fresh seeds from southern climates from time to time, or it will probably become later every year by assimilation to the climate. English seed of the first year after importation seems the best, being heavier and more free from weeds than the foreign.

Some agriculturists have objected to the practice of sowing clover with a crop of corn; they prefer hoeing the intervals between the rows of the drilled crops, by which the weeds are better kept down. They plough the land immediately after harvest, and, harrowing it well, they sow clover and grass seeds, which come in nearly as soon the next year as if they had been sown in the preceding spring; and the land, when broken up, is in a much cleaner state than if the clover had been sown with the corn. If this be not an improvement in the system, it is at least worthy of notice, and experience alone can decide whether the additional expense of ploughing is repaid by the improvement in the crop.

In France, and in the United States of North America, gypsum is considered as a specific manure for clover. It is sown by hand over the plant in spring; and in some situations the advantage is evident, in others scarcely observable. The quantity used is from three to eight bushels of finely powdered gypsum per acre.

On good land, an acre of clover will produce as much as three tons and a half of dry hay; that is, two tons the first cutting, and one and a half the second. Greater crops are obtained on very highly manured land. The value of a ton of clover-hay to feed horses with is about 15 or 20 per cent. more than good meadow-hay. It is not however so for good milch cows.

When clover is intended to be left to ripen its seeds, it should be mown early, or fed off by sheep in May. The first crop is seldom free from various seeds of other plants which rise among the clover; by feeding it down or mowing it these are destroyed, and the clover, which grows more rapidly than most other plants, rises again without any mixture of weeds. When the blossom is thoroughly withered, and the seed is nearly ripe, the clover is mown and left to dry on the ground without much shaking. In very dry weather it may be housed or stacked in a week; but the process is much retarded by showers and want of sunshine. It is, therefore, only in the drier parts of the island that clover-seed repays the expense and risk of cultivation, especially as it is well known that the subsequent crop suffers if the clover is allowed to stand for seed. It is seldom, therefore, that more seed is saved, even in the most favourable situations and seasons, than is required for the farm or immediate neighbourhood. The demand from the north, where clover is sown to a great extent, could not be supplied without a considerable importation from abroad; and the importation of clover-seed from Belgium and Holland is very considerable, as it is more advantageous to purchase foreign seed than to raise it, except in the case of the *Trifolium incarnatum*, which produces early and abundant seed. Foreign clover-seed should be well examined when it is purchased, as it frequently contains the seeds of docks and other noxious weeds. The usual mode of doing this is very simple. The thumb is moistened and pressed on the sample, some of the seeds adhere, and when it is turned up the quality is distinctly seen by the colour and plumpness of the seeds. If any seeds of weeds are in it, they must be detected after a few insertions of the thumb. As the calyx of the flower of clover envelopes the seed closely, it is difficult to separate them. Threshing-machines for this purpose are in use; but if the heads, after being separated from the haulm, are put together in a heap and pressed, a slight fermentation takes place, and this makes the calyx brittle, so that it breaks into dust, and the seed comes out readily; it is then easily cleared by the fan.

When the seed is not intended for the market, the trouble of clearing it of the husk may be saved, especially in the *Trifolium incarnatum*. It will grow as well when sown with the husk as when cleaned; and it is easy to find the proportion required to be sown in that state by allowing for the weight of the husk.

CLOVES. [CARYOPHYLLUS.]

CLUB is defined by Johnson to be "an assembly of good fellows, meeting under certain conditions;" but by Todd, "an association of persons subjected to particular rules." It is plain that the latter definition is at least not that of a club as distinguished from any other kind of association, although it may not be more comprehensive than is necessary to take in all the associations that in modern times have assumed the name of clubs. Johnson's, however, is the more exact account of the true old English club.

It might not be quite safe to make a positive assertion as to the antiquity either of the name or the thing in England. But the earliest clubs remembered in our popular literature date about the end of the 16th or the beginning of the 17th century. It was then that there was established the famous club at the Mermaid Tavern, in Friday Street, of which Shakespere, Beaumont, Fletcher, Raleigh, Selden, Donne, &c., were members.

Ben Jonson had another club, of which he appears to have been

the founder, that met at another well-known tavern, called the Devil Tavern. It stood between the Temple Gates and Temple Bar. It was for this club that Jonson wrote the 'Leges Convivales,' which are printed among his works.

It seems to have been not till a considerable time after this that political clubs first came into vogue.

In the 'Spectator,' No. 78, Addison makes mention of "the club, or rather the confederacy, of Kings. This grand alliance," he observes, "was formed a little after the return of King Charles II., and admitted into it men of all qualities and professions, provided they agreed in this surname of King, which, as they imagined, sufficiently declared the owners of it to be altogether untainted with republican and antimonarchical principles." A famous political club of those days was the King's Head Club, which is alluded to in Tate's continuation of Dryden's 'Absalom and Ahithophel.' It was a whig club; and the badge of its members was a green ribbon, in opposition to the Tories, who wore a scarlet ribbon in their hats. (See Dryden's Works, by Scott, vol. vii. p. 154, and vol. ix. p. 380.)

The great age of clubs, political, literary, and of every other description, was the early part of the last century. Then flourished, among many others, the Brothers' Club, in which were associated Harley, Bolingbroke, Swift, and the other most distinguished literary and political characters of the day: the famous Scriblerus Club, of which Pope, Swift, and Arbuthnot were the leading members: the October Club, of the original institution and subsequent history of which an account may be found in Swift's 'Four last Years of the Reign of Queen Anne,' and also in a satirical pamphlet entitled 'The Secret History of the October Club, from its original to this time, by a Member,' 8vo, London, 1711: the Hanoverian Club: the first Beef-Steak Club, of which Mrs. Woffington, the actress, was president, being the only female member, and Richard Estcourt, the comedian, provisor, wearing in that character a small gridiron of gold, hung round his neck with a green silk ribbon; and, above all, the celebrated Kit-Cat Club, which is said indeed to have been instituted at the time of the trial of the seven bishops, in the reign of James II., but was in its greatest glory in that of Queen Anne; and a most interesting memorial of which, when at its most flourishing period, exists in the famous series of portraits of the forty members, painted by Sir Godfrey Kneller for Jacob Tonson, the bookseller. These Kit-cat portraits, as they are called, are now the property of Tonson's representative, Mr. W. R. Baker, of Bayfordbury, Herts.

In 1735 the second Beef-Steak Club, which has embraced among its members the most eminent public characters that have appeared since its institution, originated with Rich, the pantomimist, and the Earl of Peterborough. For an account of the circumstances, see an entertaining work entitled 'The Clubs of London,' 2 vols., 8vo, London, 1828.

Of clubs of more recent institution, the most famous is that called by its founders and members "The Club," but which is commonly known as the Literary Club, established in the year 1764, of which Johnson, Boswell, Burke, Reynolds, Goldsmith, and other well-known names, were in the original list of members. Along with this may be mentioned the Essex Head Club, also founded a few years after by Johnson. It took its name from the tavern at which it met, in Essex Street. One of the most successful literary clubs of modern times was that called the King of Clubs, which began about the year 1801, and used to meet at the Crown and Anchor, in the Strand. An account of it is given in the second volume of the 'Clubs of London.'

The modern subscription houses which go by the name of clubs, such as the Athenæum, the University, the Senior and Junior United Service, and others of the same description, are in no other respect clubs, according to the ancient English understanding of the term, except that every member must be balloted for, or admitted by the consent of the rest. And little more of the true character of a club belongs to those numerous political associations known as the Whig Club of Brookes's, the club at White's, the Carlton Club, &c. Political associations, in imitation of those existing in England, were formed at Paris in the earliest stage of the French revolution, and assumed the English name of clubs. The Breton Club, the Jacobin Club, the Club des Feuillans, and others, performed an important part in the various scenes of that extraordinary drama.

CLUNY, ORDER OF MONKS OF; a branch of the Benedictines. Their original abbey was situated at Cluny in the department of the Saône, and they were distinguished as being reformers of the Benedictine order in 927, most strictly observing the rules as prescribed by its founder. Under the name of Cluniacs they became very popular, and by the 12th century they numbered 2000 cloisters in various parts of Europe. William, Earl of Warren, son-in-law to William the Conqueror, brought these monks into England, and built their first house at Lewes, in Sussex, about A.D. 1077 or 1078; and in the latest edition of Dugdale's 'Monasticon,' forty-two are mentioned, exclusive of three cells whose existence is not very distinctly known.

All the monasteries of this order in England were governed by foreigners, had more French than English monks in them, and were not only subject to the foreign houses of Cluny, La Charité sur Loire, and St. Martin des Champs at Paris, but could be visited by them only. None of their priors were elected by the respective convents, but were named by the above-mentioned foreign houses. They could not

receive the profession of their novices in England. To have their differences determined, they were obliged, in almost all cases, to go to their superiors beyond sea; by which means the greatest part of their revenues were carried to those foreign houses: and upon that account, during the wars with France, the different establishments of this order were generally seized into the king's hands as alien priories. After a petition from a large number of the English Cluniac monks to the parliament at Winchester in the 4th Edward III., these inconveniences were by degrees removed; and some of their houses were in that and the following reign made denizen. Bermondsey, one of the greater houses of this order, was made an abbey; and all of them were at last discharged from all manner of subjection and obedience to the foreign abbeys. Tanner says this did not take place till 1457, when a deputation from the parent abbey of Cluny, sent to Henry VI., in addition to claiming the restitution of their possessions generally, desired leave to enter all places depending upon their houses; but instead of obtaining what they asked, they were deprived of the subjection of all houses of their order in England. After a while the Cluniacs were eclipsed by the Cistercians.

Slevesholm, in Norfolk, was the last of their houses founded in England, about 1222. Four of their principal establishments were among those which Cardinal Wolsey dissolved in 1525; and the rest followed at the Reformation.

CLUTCH. [COUPLING.]

CLYPEUS SOBIESKI (the shield of Sobieski), a constellation formed by Hevelius out of some small stars below Aquila, and passing the meridian about an hour before α Aquilæ. The name was given in honour of John Sobieski III., king of Poland. None of the stars in this constellation exceed the fifth magnitude.

CLYSTERS (the Greek *κλύστηρ*), lavements, or enemata, terms bestowed upon medicinal agents introduced into the rectum, or lower bowel, with the intention of expelling its contents, or producing other local effects, but also occasionally to influence the system generally. The intestinal canal, from its commencement at the mouth to its termination in the rectum, is endowed with peculiar sensibilities; and though each portion of it has some special office, yet the whole responds to certain stimulants, whatever part they may be applied to. Thus purgative medicines may be introduced into it either by the mouth or by the rectum, and to a certain extent their action is the same, that is, both will occasion an expulsion of the contents of the lower bowel; but the secondary influence on the system will be different, inasmuch as when the purgative is given by the mouth, during the whole course of its descent it produces, according to its nature, a special action on each portion as it passes, frequently causing an increased secretion of serum, and so materially affecting the general system. But when the same substance is introduced by the rectum, it only produces a local effect, by bringing about the expulsion of the contents, and influencing the system generally only when these were of such a nature as to occasion irritation by their retention. Clysters are also employed to assist in retaining the contents of the bowels when they are expelled too frequently, as in many cases of diarrhoea. Clysters of this latter kind are likewise used to aid in retaining the contents of some of the neighbouring organs, such as of the uterus, in cases where abortion is threatened; and are also employed to allay pain and irritation in the bladder, kidneys, &c. Further, when the mouth or upper part of the throat is closed, as in spasmodic diseases, such as lock-jaw, or from tumours or paralysis, they are frequently made the vehicle for introducing either food or medicine into the system. The only other point requiring notice here is the fact that as the sensibility of the rectum is considerably less than that of the stomach, the doses of most articles given as clysters must be greater than when administered by the mouth.

Clysters are rarely, except in two instances, taken or administered without the order or superintendence of a competent medical attendant, and therefore we shall confine our observations chiefly to those two cases. The first and most common is where persons employ them for the relief of constipation; for this purpose tepid water or gruel is, by means of a proper instrument, thrown up into the rectum, and when a suitable quantity (about a pint) is used, it is generally speedily returned, bringing with it the other contents of the lower bowel. To the occasional use of such means no objection can be urged; but if employed habitually, and as a substitute for the efforts of nature, the greatest injury will result. Constipation does not in general depend upon a want of power in the rectum to expel its contents, but upon the use of improper diet, or a deficiency of the secretions of the upper part of the intestinal canal, such as the bile, which furnishes the natural stimulus to the intestines; and clysters never can effectually supply the want of these secretions. By the abuse of clysters, the tone of the whole alimentary canal may be lost, and the process of nutrition so impaired that wasting and other serious consequences have followed. Clysters even of the mildest kind should therefore be restricted to the accomplishment of temporary and occasional purposes. At the commencement of fevers and other inflammatory complaints, the speedy evacuation of the contents of the rectum is desirable; and where medicines cannot be taken by the mouth, owing to the irritability of the stomach causing their rejection, clysters of purgative substances, such as castor oil, or infusion of senna with sulphate of soda, may be used. For the relief of spasmodic diseases, clysters of the fetid gums, such as

assafoetida, or of oil of turpentine, may be used. Sometimes tobacco in the form of infusion or of smoke is employed; but this requires the greatest care. The second case to which we have alluded, in which clysters are employed without medical superintendence, is that of tobacco-smoke thrown into the rectum of drowned persons: a more hurtful measure cannot be adopted; it is now abandoned by all intelligent persons.

Where clysters are employed to allay pain, or arrest premature action of the uterus, they generally contain tincture of opium, and are of small bulk; about a quarter of a pint of starch serves as the vehicle. Where nourishment is the object, they are also of small bulk; about half a pint of beef-tea alone, or with powdered cinchona bark, and a few drops of laudanum. Substances introduced into the rectum in a solid form are called suppositories.

CNICINE ($C_{10}H_{26}O_{14}$), an active principle found in the sub-order *Cymarocephalæ* of the Composite order of plants. It is neutral and bitter.

COACH. For a variety of information relating to the introduction, commercial importance, and legislative supervision of hackney coaches, mail coaches, stage coaches, cabriolets, Irish cars, and similar means of public conveyance, see STAGE CARRIAGE.

COACH-MAKING. The mechanical details involved in the manufacture of a coach or other vehicle depend, for any peculiarity which they present, rather on the choice and combination of materials than on the actual working processes. There are however a few points which merit attention both as to materials and to processes.

The timber employed in coach-building comprises ash, beech, elm, oak, mahogany, cedar, deal, pine, fustic, larchwood, and birch. Mr. Adams ('Treatise on Pleasure Carriages') gives the reasons for the selection among these species of wood, according to the purpose to which it is to be applied. The timber mostly employed is English-grown ash. The "hedge-row" ash, growing in open spots, is of slower growth, but is much firmer, stronger, and tougher than that of the "coppice," and is therefore preferred to it for making the heavy framework of a carriage. Ash is rather a tough and fibrous than an elastic wood, and is well calculated to bear the concussions to which the supporting framework of a coach is exposed; it is best fitted for use when arrived at maturity, but before it has attained its extreme size; it is sometimes white at the heart, sometimes red, the former being best fitted for the purpose in view; it is sometimes so wrinkled in grain as scarcely to be planed smooth, and is then in its toughest state; it acquires by steaming a plastic property, which enables it to be bent to a form suited for carriage-timbers. These various qualities, together with the absence of any tendency to twist or warp, render ash better fitted than any other kind of timber for the skeleton framework of a carriage. *Beech* is a timber used only in building carriages of an inferior kind, since it cannot well bear alternation of air and moisture. *Elm* is used largely for strong planking. Of the two kinds, "hedge-row" elm is more employed than "wych" or "wick" elm. The grain of this wood is curly and wavy, difficult to work, brittle, and apt to split; but when once brought into workable form, elm possesses great strength, especially for the naves of wheels. *Oak* is not employed to any considerable extent in coach-building; but it forms the spokes of wheels [WHEEL], and is used in some cases as a thin planking or "wainscot." *Mahogany* is chiefly in request for forming the panels or broad plain surfaces of the body of a coach. In the use of this kind of wood there is a difference between the cabinet maker and the coach-builder: the former prefers "Spanish" mahogany, on account of the beautiful curled grain which gives such diversity of light and shade; whereas the coach-builder distrusts it, because the curled grain prevents it from being bent into the curvatures required in coach-making. "Honduras" mahogany can be procured in planks four feet in width, perfectly straight-grained, and free from knots and blemishes, and is therefore a kind of timber well fitted for bending. *Cedar*, of considerable width and having a coarse grain, is sometimes used instead of mahogany for coach-panels, when they are to be covered with leather: it is too porous to receive a painted surface. *Deal* is employed for the flooring of carriages, and also for panels which are to be covered. *Wide American Pine*, cut into very thin boards, is used for the roofing. *Fustic*, a hard yellow wood obtained from Central and South America, is sometimes employed for the naves of wheels which are intended for hot climates, as being less liable to shrink than English timber. *Lancewood*, a yellow, close, straight-grained, elastic but brittle wood, was formerly much used for the straight shafts of carriages; but when curved shafts became general, the employment of this wood for the purpose lessened. *American Birch* is much used for flat boarding, on account of its great width, its homogeneous substance, its freedom from rents, the smallness of its pores, its ready yielding to the plane, and the non-appearance of the grain when painted; it is however brittle, and cannot be bent like mahogany for panels. *Sycamore*, *Chestnut*, and *Plane-wood*, are occasionally used as substitutes for some of the above-mentioned woods.

In working up these varieties of timber, tools and processes are employed similar to those witnessed in many other trades. In the first place, a "mould" of the coach body is prepared from the pattern, as in the preparatory stage of ship-building; that is, thin pieces of wood are so cut out as to denote the size, form, and curvatures of all the separate parts of the coach; and these afterwards act as guides in

cutting and shaping the timber. The working-operations are of two wholly distinct kinds, carried on by different sets of workmen: one relates to the "body," and the other to the framework or "carriage;" the former depending more upon delicacy, and the latter upon strength. In bending thin pieces of timber to form curved panels, the wood is wetted on the side which is to be convex, and heated on that which is to be concave: the unequal expansion of the two surfaces—or rather, the expansion of the one and the contraction of the other—produce the curvature, and it is the workman's business to secure this curved form when once obtained. With a few exceptions, the processes connected with coach-body making may be regarded as very similar to those of cabinet-making.

In the making of the carriage which supports the body, the flat surfaces are so few in number that the plane is scarcely employed; after the saw, the chief cutting instrument is a hand-tool resembling a spoke-shave. The complexity of the framework, and the number of pieces which compose it, depend a good deal on the circumstance whether the carriage has four wheels or only two, and whether drawn by one or two horses. In the *Dennet* and the *Stanhope*, two-wheeled vehicles drawn each by one horse, there is very little underframing. In the *Tilbury* and the *Cabriolet*, pliable leathern braces are introduced between the springs and the body of the vehicle. All these four have shafts; but in the *Curricie*, a two-wheeled vehicle for two horses, now almost extinct, there were no shafts; the body was suspended on a frame consisting of two side-pieces and two cross-bars at each end; a pole inserted in this frame served to yoke the horses to the vehicle. Where there are four wheels, the underframing is more complicated, since the wheels have to be connected one with another, and also with the body. In some vehicles of this kind, there are elliptical springs beneath the body and the axle; while in others, besides these springs, there are pliable leathern braces to connect the body with the under-framework; in which case the framework which supports the fore and hind springs is connected together by a long central piece of timber called the *perch*. Occasionally this perch is made of iron, and is bent into a form called the "crane-neck," as a means of enabling the coach to be turned more readily in a narrow street. The general class of four-wheeled carriages for two horses, such as the coach and the chariot, have double sets of springs: namely, horizontal springs immediately on the axles, to support the carriage and to intercept the concussion; and circular upright springs to sustain the body. If made close, such carriages comprise the varieties of the Coach and the Chariot; if to open occasionally, the Landau and the Landaulet; if to remain permanently open with a leathern hood or head, the Barouche and the Barouchet; and a modification of this latter kind, the *Britzscha*. All these varieties of form render necessary corresponding changes in the formation of the framework beneath. The form and nature of the springs above alluded to are described in SPRINGS. Many coach-makers now make use of gutta-percha and vulcanised India-rubber, in parts where toughness and elasticity are needed.

The arrangements of the under parts of the mechanism depend a good deal on the facilities afforded for turning the coach. In a four-wheeled carriage there is an axle connecting the two fore-wheels, and another connecting the two hind-wheels; and if these two axles were so fixed as to remain constantly parallel, the carriage could not turn. In practice, the front axle is made to turn upon a pivot, and the wheels connected with it are made small enough to go under the framework of the carriage during the act of turning. It is for this reason, and this alone, that the front wheels are made smaller than the hinder ones; and as a great disadvantage in draught is thereby occasioned, various contrivances have been adopted for rendering the use of somewhat larger wheels practicable. Sometimes the body of the carriage is raised to a greater height; sometimes a portion of the under part of the body is cut away, to leave room for the turning of the wheel. It was as a means of remedying these inconveniences that Mr. Adams proposed the "aequirota" construction of carriages. As the inequality in the sizes of the fore- and hind-wheels is adopted solely as a means of enabling the vehicle to be turned round, Mr. Adams sought for some mode of enabling this turning to be effected even when all the four wheels are of equal size. This he does by having the carriage so divided in the middle as to turn upon a pivot; or rather, the pivot, or perch-bolt, which in a common carriage is placed immediately between the two front wheels, is on the aequirota principle placed much farther back, by which the fore-wheels have so large a radius in turning that they do not touch the body, and may therefore be made of equal size with the hinder wheels. The mode of adjusting this pivot depends upon the kind of carriage. In a phaeton, which is an open four-wheeled carriage with two seats, the front one higher than the lower, the hinder half of the body is hinged to the front half. In a chariot or a coach, the coach-box is connected with the framework of the front wheels, and the body with that of the hind wheels, and there is a pivot which connects the two halves together. There is great ingenuity in this aequirota system, but it has not come largely into use.

The axles of a carriage form an important part of the manufacture, since they are the medium of communication from the wheels to the body. When this part of the mechanism was made wholly of wood, its general designation was "axle-tree;" but iron is now more extensively

used, and the name "axle" is given to it. Formerly the axle was made to revolve with the wheels, but now the wheels are generally made to revolve on and not with the axle. There are three parts in the axle,—the two "arms," which pass into the naves of the two wheels, and the "bed" or central part, which connects the two arms. The adjustment at the nave or centre of the wheel requires very careful management; and it is to this point that Collinge's "patent axle" chiefly relates. In earlier modes of construction a ring was put within the hollow of the nave, and the end of the arm of the axle worked within this ring,—an arrangement which was intended to prevent the too rapid wear of the wood by the friction of the axle. In the present practice, however, the axles are fitted with iron boxes adjusted to the arms. To lessen the friction arising from the two surfaces working together, black lead, soap, grease, or oil is used; and it is partly on account of the ingenious way in which this lubrication with oil is effected, that Collinge's "patent axle" is so much employed. Besides the mechanism for connecting the axle with the wheel, there is contained a little cup for holding oil; and as the wheel rolls along, this oil is pumped or drawn out of its receptacle, and made to lubricate the adjacent surface.

In a well-finished coach, the *leathering* and the *painting* are among the more important processes after the wood and iron work are completed. The former of these is somewhat remarkable. In the common kinds of vehicles the wood and iron are coated with paint laid on to a considerable thickness; but for the better kinds, leather is applied to the roof, and the upper part of the back, front, and sides, previous to the process of painting; this is done chiefly to shield the wood-work from the alternations of heat and rain. A singular example is here shown of the pliability of leather; for one hide, without seam, knot, or joining, is made to cover the whole. "The hide, which is of a large size and sound quality, is first thoroughly moistened and thrown over the top of the coach, the edges hanging down on all sides. The currier then rubs or presses it down all over the roof, until it lies close and even in every part. He next proceeds to one of the sides, and in like manner rubs and scrapes the leather till all irregularities disappear. The leather is in that soft and pliable state that it will yield to the movement of the tools, and enable the workman to fit it to every part of the coach with perfect closeness. A little consideration must show that a superfluous fold of leather will occur at each corner; yet by working it towards a central point at the back or front, the currier succeeds in erasing or pressing out all irregularities, and in producing a surface sufficiently flat and smooth for the subsequent operations of the painter. The division between the upper and lower portions of a coach is usually covered by beading of some kind or other, and the leather is trimmed or cut to this line of division." ('Penny Magazine,' No. 625.) Any cut or crack in the leather, however small, would be fatal to the success of this remarkable mode of covering coaches.

A coach receives a far thicker coating of paint than the wood-work of a house, since it could not else admit of the very high polish to which it owes so much of its beauty. The principal plain surfaces, such as the doors and panels, receive ten, twelve, or even fifteen distinct coatings, each one thoroughly dried before the next is applied; and at intermediate times all the roughnesses derived from the paint are smoothed down by pumice-stone, rotten-stone, and other like substances. The leathered top, in the best coaches, sometimes receives as many as twenty-five coatings of paint. The paint, which is formed from nearly the same materials as that used for house-painting,—namely, mineral colours, linseed-oil, and turpentine,—is of a white colour for the earlier coats, a yellowish tint for those next applied, and depends for its tint in the later coatings on the taste of the maker. All these several coatings being dried and smoothed, the surfaces receive six or eight applications of copal varnish; and it is the subsequent polishing of this varnish which imparts the smooth, lustrous, and beautiful appearance to the panels and plain surfaces.

Mr. Hooper, a practical coach-builder, in a paper recently read before the Society of Arts, drew attention to several interesting matters connected with his art. Of these, we will notice three,—relating to the classes of work-people employed in coach-making, the kinds of lace and silk required in finishing a carriage, and certain desiderata among coach-builders. On the first point he said: "Carriage-workmen are divided into separate classes and trades. There are *body-makers*, who form and make the part in which the persons sit; *carriage-makers*, who make the under works, apply the parts necessary for backing or turning the carriage, fix the axles and springs, &c.; *wheelers* or *wheelwrights*; *joiners*, who make the glass-frames, blinds, boxes, trunks, &c.; *fitters*, who fit and suspend the bodies on the under works, and apply the various parts furnished by special manufacturers, such as lamps, handles, &c.; *body and carriage painters*; *trimmers*, who fit up the insides of carriages, and fix the silks, cloth, and laces in the necessary parts; *leather-workers*, divided into *cutters*, *sewers*, *seat-trimmers*, and *harness-makers*, according to the different works they are engaged upon; *smiths*, divided into *carriage-smiths*, *body-smiths*, *tyre-smiths*, and *spring-smiths*; *vicemen*, who chisel and file the iron-work made by the smiths; *carvers*; *sawyers*; *polishers*, who produce the brilliant polish on carriage panels; *herald painters*; *caners*, usually women, who interlace the neat cane-work now so fashionable on carriage panels; and *liners*, women who sew together the cloth, silk, lace, &c., after being cut out by the trimmers." Concerning the silk and lace used in coach-making, Mr. Hooper said: "Formerly a kind of silk called *lutestring* was in use.

This was superseded in England by a strong ribbed silk called *tabaret*. After a time, this *tabaret* was copied in France, where the manufacturers considerably improved it by overcoming a difficulty, and producing a figure on the surface. This, in its turn, was copied in England (about 1848), with much success, and has now almost superseded all other kinds for carriages; it is called *reps* in France, and *boscattelle* in England. The improvement in this kind of silk goods has been so rapid in England for several years past as to have overtaken the French fabricants, with a good chance of surpassing them in quality at a lower price. Carriage laces appear to have been made for many years in this country of a quality far superior to the foreign laces; they [the foreigners] have, however, now succeeded in making them of excellent quality. The Germans have been introducing a considerable quantity of good lace into this country for some months past, at a very reduced price compared to English-made laces; this however will probably be soon counteracted, as it has caused some enterprising manufacturers in Coventry to establish improved looms for this department of weaving, and to produce goods of equal quality at somewhat lower prices." Mr. Hooper's remarks on desiderata were to the following effect: "We are in want of several improved materials and appliances to facilitate the manufacture of carriages. Among the former, are,—colourless oils for painters' use; a colourless varnish (all the copal varnishes now in use having a brown tinge, which is injurious to delicate colours); a durable ultramarine blue; and cheaper and more durable laces. Among the latter [class of desiderata], is a machine for sewing leather for carriages and harness: though various attempts have been made, they have up to the present time been unsuccessful, as they will not work with a strong waxed thread, or draw the stitches sufficiently tight. A machinist producing such a machine at a reasonable price would have a large demand for them; seeing that, besides the great quantity of leather-sewing required for carriages and carriage-harness, saddlery, army accoutrements, and military harness would lay claim to its assistance."

COAGULATION, the solidification of a liquid produced without evaporation and without crystallisation. It is also often effected without reducing the temperature of the substance coagulated, in which it differs from mere congelation.

Coagulation occurs in various ways in different fluids. Thus when albumen, or the white of egg, is heated, it is rendered solid, or it coagulates. The spontaneous coagulation of the blood, by which it is resolved into serum and coagulum has already been noticed. [BLOOD, NAT. HIST. DIV.] The cause of the coagulation of casein by the action of rennet on milk, is as yet unexplained. Acids induce the curdling of milk by neutralising the alkali by which the casein is held in solution.

There are some cases of pure chemical action which resemble coagulation in appearance; when, for example, solutions of sulphate of soda and nitrate of lime are mixed, a sudden solidification takes place; but this is a case of confused crystallisation, and not of coagulation.

COAL TAR. When coal is heated in close vessels [GAS, MANUFACTURE OF] a large quantity of gas is evolved, from which on cooling there separates out a dark coloured, badly smelling, treacle-like substance, called coal-tar. It possesses very considerable interest from the fact, that by distillation it furnishes a number of compounds now almost indispensable in the arts and manufactures. For this purpose large quantities of it are heated in immense iron stills. The portions that first distil over, constitute, when rectified, *coal-naphtha*, so important as a solvent of india-rubber and gutta-percha. The second portion of the distillate, about 30 per cent., is technically known as *heavy naphtha*, *coal oil*, or *dead oil*: it is used as a lubricating agent, and on account of its antiseptic properties is employed to preserve timber; thus railway sleepers soaked in it resist the action of air and moisture for a far greater length of time than usual. Coal-oil is also largely used for burning into the lampblack with which printer's ink is made. The residue in the retort, after the naphtha and coal-oil are entirely volatilised is *pitch*, used in forming asphalt pavements, and in the manufacture of black japan for varnishing iron-work.

Coal-tar mixed with the coal dust formerly wasted in mining operations forms an excellent artificial fuel; it is usually rendered compact and portable by being pressed into the form of square blocks.

Finally, colouring matters and perfumes may be obtained from coal-tar, though at present not in all cases economically.

Naphtha, coal-oil, and pitch, are each of them mixtures of several definite chemical compounds, and by careful rectification, &c., may be separated from each other. They are usually divided into three classes, basic, acid, and neutral. The following is a list of those that have been examined:—

Bases.	Acids.
Picoline.	Acetic.
Leuconine.	Carbolic.
Aniline.	Brunolic.
Pyridine.	Rosolic.
Neutral substances:—	
Liquid.	Solid.
Benzole.	Paraffin.
Toluole.	Naphthalin.
Cumole.	Paranaphthalin.
Cymole.	Pyren.
	Chrysen.

They will be found more fully described in their respective alphabetical places.

Reichenbach has also noticed, and partially examined, three other substances: *pittacal*, a deep blue coloured solid; *picamar*, a bitter oil, sp. gr. 1.1; and *cedriret*, which crystallises in orange-red needles from a solution of persulphate of iron. Greville Williams has also isolated several radicals of alcohols, or their hydrides, including *tetryl* and *amyl*.

COAL TRADE. In the article COAL, COMPOSITION OF, in the NATURAL HISTORY DIVISION of this Cyclopædia, an account is given of the chemical constituents of different kinds of coal; in the article COAL FIELDS, in the same division, a full description is given of the chief deposits of coal in our own and in foreign countries; lastly, under the head of MINING, COAL, in the present division, will be found a description of colliery operations. In the present place, therefore, it will suffice to trace some of the more remarkable features in the coal trade of this country; with a notice of some of the circumstances which have led to a rapid augmentation of that trade.

In 1816, a committee of the coal-owners of Northumberland and Durham was commissioned to inquire into the quantity of coals at that time sent by road and canal, from the pits of these two counties to other parts of the kingdom. The quantity was ascertained to be nearly 11,000,000 tons. But this estimate took no account of the sea-borne coal to London, nor of the coal consumed in and near the busy towns of the north. Twenty-five years ago it was estimated that Sheffield alone consumed half a million tons, drawn from neighbouring pits; and that the iron-works of the midland counties consumed five million tons. The statistical returns were, however, very inconclusive; for the estimates of total consumption in the United Kingdom, in all localities and for all purposes, varied between the wide limits of fifteen and thirty million tons. About the year 1830, a great authority on mining subjects, Mr. Taylor, made the following estimate:—

	Tons.
Coals sent coastwise from Northumberland and Durham	3,300,000
Home consumption in Northumberland and Durham	660,000
Produce of other counties for domestic purposes	7,920,000
Consumed in iron-works and Cornish mines	3,000,000
Exported to Ireland	700,000
	15,580,000

This was exclusive of the exports to foreign countries. Other inquirers, about the year 1835, felt assured that the quantity was higher than Mr. Taylor had estimated. One tabulation, carefully prepared so far as data were obtainable, gave the following result:—

	Tons.
Sent coastwise from Northumberland and Durham	4,368,000
Home consumption in Northumberland and Durham	870,000
Produce of other counties for domestic use	10,480,000
Consumed in iron-works and Cornish mines	6,000,000
Exported to Ireland	1,000,000
Waste by screening	6,630,000
	29,348,000

Later estimates, based on surer grounds, we will advert to presently.

It was long considered by the legislature politic to check the exportation of coals to other countries; both through fear of exhausting the mines, and because it was imagined that our superiority as manufacturers might be endangered. Coal was also, on many occasions, made a source of revenue to the state, a source of revenue to the corporation of the city of London, and a perquisite to certain pampered minions of the court. The national tax was sometimes on exported coal, sometimes on coal carried coastwise. The London tax is a corporate privilege, granted by virtue of several acts of parliament, for several alleged reasons; it amounts to about a shilling a ton, and is levied on all coals brought into London, or within a certain radial distance of it. There is a probability that this tax, in its appropriation, if not also in its amount, will shortly undergo modification. The Tyne tax, or Richmond tax, was a perquisite granted by letters patent from Charles II. to the Duke of Richmond, amounting to one shilling per chaldron on all coals shipped from the Tyne to the Thames; the descendants of the duke received this perquisite until the year 1799, when it was found to amount to about 21,000*l.* per annum; it was commuted for a perpetual annuity of 19,000*l.*, chargeable on the Consolidated fund.

The coal-owners of Northumberland and Durham, looking to London as its best customers, maintained for many years a remarkable compact, tending to keep up prices. Railways have now nearly broken down this monopoly, but it may be well briefly to state its nature. In 1771, the owners of the greater part of the collieries in the counties of Durham and Northumberland entered into a mutual agreement, under the denomination of "The Limitation of the Vends." The object of this compact was to apportion among the different collieries the quantity to be raised and sold, according to the quality of the coal and the power of raising it, and with reference also to the probable demands of the different markets in the kingdom. A representative was named for each of the collieries: these representatives met together, and from amongst them chose a committee of nine for the Tyne, and seven for the Wear. This being done, the proprietors of the best coals were

ARTS AND SCI. DIV. VOL. II.

called upon to name the price at which they intended to sell their coals for the succeeding twelve months; according to this price the remaining proprietors fixed their prices. This being accomplished, each colliery was requested to send in a statement of the different sorts of coal they raised, and the powers of the colliery, that is, the quantity that each particular colliery could raise at full work; and upon these statements the committee, assuming an imaginary basis, fixed the relative proportions as to quantity between all the collieries, which proportions were observed, whatever quantity the markets might demand. The committee then met once a month, and according to the probable demand of the ensuing month they issued so much per 1000 to the different collieries. This demand was determined wholly by the price in the London market. If this had been greater during the previous month than the price fixed by the coal-owners, as already explained, added to the freight and other charges of conveyance to London, permission was given to raise a larger quantity; and on the contrary, if the price had been below a remunerative one, thus calculated, then the supply was limited till the requisite price was reached. In the agreement entered into among the owners of collieries, it was stipulated that no one without leave of the committee should sell below the fixed price agreed on as the price to be charged by such colliery; and arrangements were made for enforcing penalties for any breach of this agreement. The policy or impolicy of the "Limitation of the Vends" was for many years very fiercely contested,—the colliery interest regarding the practice from a protective point of view: while the inhabitants of the metropolis were naturally favourable to a free-trade policy. It is unnecessary to follow the line of argument used by either side; for the system has gradually yielded to the power of railways, which now bring up coals cheaply to London, from districts which were formerly wholly shut out from this important market.

Another regulation affecting the coal trade from the Tyne and the Wear was established by Act of Parliament (6 Geo. IV. c. 32), under the provisions of which every ship must be loaded in her turn; and if any colliery refuse to sell, a penalty is imposed of 100*l.* This regulation was, however, evaded by the coal-owners towards ships the owners of which refused to be bound by their regulations in the port of discharge. The mode of evading it was to fix an exorbitant price upon their coal, which might be done although a price below the regulation was not allowed; by this means the vessels were either brought into conformity with the regulations in the port of discharge, or forced out of the trade. The factors and colliery-owners, again, still find it convenient among themselves to make regulations concerning the number of ship-loads of coal that shall be offered for sale on one day, and the order in which the several collieries shall be represented; but all such compacts, like the limitation of the Vends, have been much affected by the extension of railways.

In 1836 there were 47 collieries on the Tyne, 17 on the Wear, and 16 on the Tees. The Tyne and the Wear were at that period jealous of the Tees, which was beginning to ship large stores of inland coals brought down to Stockton by railway; and attempts were made, with partial success, to check the further construction of railways in the two counties. Seven years afterwards, in 1843, the colliery proprietorships were ranged under four classes, according to the scale of the operations. The 1st class comprised four great concerns, headed respectively by the Marquis of Londonderry, the Earl of Durham, Lord Ravensworth, and the Hetton Coal Company. The capital sunk in each of these concerns was supposed to be not less than half a million sterling; they each comprised from six to twelve separate mines, and all the necessary engines, waggons, horses, &c.; and they were believed to realise a profit on an average from 35,000*l.* to 45,000*l.* per year each. The 2nd class comprised companies or partnerships whose sunken capital ranged from 100,000*l.* to 200,000*l.* The 3rd class included those concerns which had only a single pit each, and whose capitals ranged between 40,000*l.* and 60,000*l.* The 4th class, humbler but more numerous than any of the others, comprised those which had a capital ranging from 8000*l.* to 30,000*l.* In that year, in Durham county, there were more persons employed under ground in coal-mines than above ground in agriculture. The following figures referred to a particular day in the year 1843, and to all the collieries on the Tyne, Wear, and Tees:—

	On the Tyne.	On the Wear and Tees.
No. of collieries	41	29
No. of pits	92	100
Average depth, in fathoms	85	75
No of men and boys employed	12,833	12,937 (in 27 collieries)
Engine-power in pumping water	4,888 horses	9,707 (in 23 collieries)
Engine-power in raising coals	4,782 "	
Coal raised per annum	2,468,481 tons	2,355,486 (from 22 collieries)
Highest price at that date	10 <i>s.</i> 1½ <i>d.</i> per ton	11 <i>s.</i> 6 <i>d.</i> per ton
Lowest price at that date	7 <i>s.</i> 1 <i>d.</i> "	8 <i>s.</i> 6 <i>d.</i> "

The coal-mining arrangements, in relation to wages and labour agreements, differ in different counties. In South Staffordshire and the neighbouring coal-fields, the "Butty" system is extensively acted on. This consists in the miners being the servants, not of the proprietor or lessee of a colliery, but of a contractor called a "butty," who

engages with the proprietor of the mine to deliver the coal at so much the ton; hiring the labourers himself, using his own horses, and supplying all the tools necessary for working the mines. These butties have in general been working miners, who, by the accumulation of some little capital, or by the assistance of relations, are enabled to engage a pit, with or without partnership with other persons, and to enter into a bond to raise the coal at a given price per ton. "The butty," says Mr. Tancred, in a Report on the coal trade, "has become the middleman or task-master, and the pit's company his hired labourers, from whom it is his interest to squeeze out as much profit by any and all means as circumstances will allow. The man of property, who possesses the royalty, sinks the pits, and erects the machinery, and whose position therefore in society would ensure in general humane and liberal treatment of his labourers, is by the intervention of a butty entirely disconnected with them; he neither hires nor dismisses them from his mine, but hands the whole concern over, as far as the employment of the labouring classes is concerned, or any interest in their welfare as his servants, to an inferior." The miners entertain a bitter dislike to the "butty" system, and many of the proprietors are endeavouring to abolish it. In the Northumberland and Durham district, the relation between the proprietors and the miners is more direct and intimate. No middlemen or contractors are employed; the overseers, viewers, and other intermediate officers, are paid by regular salaries; and the working colliers receive in cash from the proprietors, once a fortnight, the amount of their earnings. There is a bond or agreement between the parties, differing from the "butty" system of Staffordshire, and also from the "tutwork and tribute" system of the Cornish mines. [MINING.] This bond is annual, and by its terms the miner is ensured a minimum amount of wages, generally to the extent of seven or eight days per fortnight, which the owners are bound to pay the men whether the mine be working or not; beyond this minimum, whatever work the miners may do is paid for at a stipulated price. The wages are paid for the quantity of coals raised. This northern system however, like the limitations of the vends, has been much affected by railway rivalry.

Until recent years, women and children were largely employed in coal-mines. In Northumberland and Durham there were nearly as many women and children as men in the pits; and in Lancashire and Yorkshire a much larger ratio. The statements made public concerning the condition and treatment of these women excited much attention about eighteen years ago, and led to the passing of an Act of Parliament in 1842 (5 & 6 Vict. c. 99), of which the following is a brief abstract: From the time of passing the Act no female, other than such as were so employed previously, was to work in any mine or colliery; and that after three months from that date, no female under eighteen years old should be so employed; nor any female whatever after March 1, 1843. After this latter date, no males were to be employed under ten years of age. No person to be apprenticed under ten years of age, nor for longer than eight years (except in the case of engine-wrights and others who are only occasionally at work under ground). Where there are vertical or other shafts, no steam or other engine to be intrusted to the care of a person under the age of fifteen; in the case of a windlass or gin worked by a horse or other animal, the driver to be considered the person in charge. After three months from the passing of the Act, proprietors of mines or collieries not to pay workmen their wages at any tavern or public-house. To enforce the observance of these regulations, the following arrangements were made: Inspectors of mines and collieries, appointed by the Secretary of State for the Home Department, are empowered to enter and examine any such works, and to report concerning them to the government; any proprietor violating the law as to the age and duration of apprenticeship, is subject to a fine varying from 5*l.* to 10*l.*; parents or guardians misrepresenting the age of children so employed are fined 40*s.*; a neglect of the clause as to the care of the shafts, and also of that relating to the payment of wages, subjects the offender to fines varying from 5*l.* to 50*l.* It was found, as might have been expected, that many young persons were for a time thrown out of employment when this act came into operation; but the evils resulting from the former system were too great to be overlooked.

The question respecting the available store of coal in this island has been much canvassed. Mr. T. Sopwith, in an Essay published in 1844 ('The National Importance of Preserving Mining Records'), remarks: "The opinion that our stores of coal are all but inexhaustible, rests wholly on assumed data, and not upon an accurate and detailed statistical account, such as alone could warrant a confident opinion. This question will ere long become a subject of serious concern, unless some measures are taken to found our calculations on a solid basis. It is an easy matter to assume that a considerable thickness of available coal extends over hundreds of square miles; but the different opinions formed by men of the highest respectability and talent, strongly prove how meagre and unsatisfactory are the only data on which these estimates are founded. It is not, however, the mere quantity of coal that is to be considered. Especial regard must be had to its quality, depth, thickness, extent, and position. Many of the inferior seams can only be worked in conjunction with those which, by their superior quality, repay the expense of working them at depths varying from 300 to 600 yards; and it may readily be conceived, that inferior coal only could not be profitably raised from pits equal in

depth to three or four times the height of St. Paul's Cathedral, unless the price of such inferior coal was raised to more than the present price of the best coal. . . . It is not the exhaustion of mines, but the period at which they can be profitably worked, that merits earnest and immediate attention." These remarks, from a man who is well acquainted with the subject, are worth more than the vague assertions made by some geologists and writers on statistics. In this as in other branches of industry, we must not only consider the possible amount of supply, but also the price at which the thing can be brought to market. It is supposed that the total yield of all the collieries in the United Kingdom is about 50 million tons yearly. In 1854 the Northumberland and Durham yield was about 14 million tons; of which, 6½ millions were shipped coastwise, 2½ exported, 2½ converted into coke, 2½ consumed locally. This produce would have covered with a layer an inch thick a road a thousand miles long by six yards broad.

In relation to the coal-trade of recent years, three circumstances must be taken into account,—the effect of the removal of the duty, in increasing the amount of export; the effect of railways, in increasing the supply and lowering the price; and the effect of screw-collier steamers, in expediting the transport and lowering the price. We shall offer a few remarks on all these points.

The coal duties were repealed in 1835, so far as concerned coals exported in British ships; while the duty on those exported in foreign ships was reduced. Great activity followed, for ships were now enabled to carry out coal instead of ballast to foreign countries. The exigencies of the state led to a re-imposition of the duty in 1842; this at once checked the foreign trade, which did not recover itself till the final removal of the duty in 1845. The trade had been gradually growing, from about 370,000 tons in 1827; 740,000 in 1835; to 1,600,000 in 1840, and 2,000,000 in 1842. The discouragement brought it down to 1,700,000 in 1844. After the final removal of the duty, the trade extended in the following remarkable way:—

1846	
1848	2,531,108 tons.
1850	2,785,301
1852	3,351,880
1854	3,640,194
1856	4,309,255
1858	5,879,779
	6,519,956

These figures are very significant, showing how rapid has been the advance in this department of our export trade. These returns include culm and coke as well as coal. The extent to which different foreign countries are our customers for fuel may be illustrated by the figures for the year 1858:—

Russia	
Denmark	314,082 tons.
Prussia	382,604
Hanse Towns	409,402
France	521,405
Spain	1,332,241
Turkey	331,818
United States	187,430
Malta	300,707
West Indies	118,325
Other countries (about)	90,134
	2,500,000

The extent to which different collieries contributed towards these figures, in 1858, may be thus shown:—

From Tyne, Wear, and Tees	3,600,000 tons
" Yorkshire	250,000 "
" Liverpool	470,000 "
" South Wales and western counties	1,400,000 "
" Scotland	380,000 "

leaving about 400,000 tons from other parts.

The London consumption of coal is by far the most remarkable feature in the trade. In 1814, when the price of coal was 13*s.* per ton at Newcastle and Sunderland, it was as high as 44*s.* in London,—so heavy was the coasting duty, and so large the profits of the colliers, owners, and all concerned. In 1834, when the Newcastle price was 10*s.* 9*d.*, the London price was 19*s.* This addition of 8*s.* 3*d.* was made up of an immense number of items, including freight, weight office, entry, City dues, metage, scorage, factorage, commission, insurance, policy duty, and delivery charges. In the year just named, London bought 2,300,000 tons of coal, which required the services of 8000 ships. In 1842 the quantity amounted to 2,700,000, in addition to a small quantity of canal. The Great Northern Railway has been the chief agent in bringing about an improved supply of coals to London; the directors made arrangements with colliery owners in Yorkshire and other counties, by which inland coals could be brought to the metropolis at a very low price: a double consequence followed,—other railway companies have adopted a similar system in relation to other counties, and the Northumberland and Durham colliery owners have been brought into a state of healthy competition. Their limitation of the vends was brought to an end in 1845, even before the railway system had developed its powers in the coal-trade. By the year 1853 the sea-borne coal the railway transport nearly reached 1,000,000 tons. In 1857 the quantities were—3,160,000 tons brought by sea, and 1,230,000 tons by railway and canal: showing a steady rise in the inland mode of conveyance.

The coals brought to London by sea are mostly in collier sailing-brigs. The competition in the trade, however, has in late years led to a new mode of transport, by screw steam-vessels. From a paper read before the Institution of Civil Engineers in 1854, it appears that, about that date, the screw-colliers in use carried about double the average cargoes of sailing-colliers, and were capable of making thrice as many voyages in a year. An average screw-collier, therefore, did six times as much work as a sailing-collier. A sailing-collier, carrying 300 tons, and making ten voyages in a year, might be bought for 1200*l.* to 1800*l.*; and six of them would about equal in cost one screw-collier, carrying 600 tons, and costing 10,000*l.* Then, on comparing all expenses attending the carrying of 18,000 tons of coal to London, those of the screw-collier amounted to 5050*l.*, while those of the six sailing-colliers amounted to 6420*l.* The sunk capital being about equal in the two cases, and the working expenses exhibiting the ratio here mentioned, the difference amounted to 1*s.* 6*d.* per ton, or 20 per cent., in favour of the screw-collier. Sailing-colliers, worked on the most approved principles, could bring coals from the Tyne to London at 5*s.* 3*d.* per ton; whereas screw-colliers could do the same work for 3*s.* 6*d.*,—the same rates being taken for both in relation to wages, provisions, and stores. It was argued, in the discussion which followed the reading of the paper here adverted to, that screw-colliers are indispensable to the serving of a steady and efficient supply of sea-borne coal to London, combined with good collier-docks at both ends of the route (such as the admirable Victoria Dock at North Woolwich). Vast fleets of sailing-colliers are sometimes detained in the Tyne by adverse winds, or by want of water on the bar; then, on a change of weather, they all set sail together, and arrive at the Thames in a very cloud of sail, where perhaps they have to beat up a hundred miles of river against wind and tide. Hence the variation of supply, followed by variation of price. The cure for this would be a powerful fleet of screw-colliers, constantly and punctually running, with commodious docks at both ends of the route, and all the best modern facilities for rapid discharge by steam-cranes instead of coal-whipping. Experience, however, has not altogether confirmed the anticipations of the steam-collier projectors. The sailing-colliers, it is found, can yet do the work more cheaply on the whole.

The question has been much discussed, whether the use of screw-colliers would realise one of the objects sought to be attained by vastness of size in reference to the ship *Leviathan*, or *Great Eastern*. Ordinary steamers, going to the Cape, to India, or to Australia, are obliged to stop on the way to take in coals; and as native coal is not found on the coaling stations, a supply has to be taken from England. This supply is conveyed by sailing-colliers, and the price of coal hence becomes enormous at the more distant stations. To obviate this evil, the projectors of the *Great Eastern* planned a ship so large that it can carry a supply of coal sufficient for a voyage to Australia and back. The question now is, whether the capital expended in building the coal-storing part of this enormous ship would not be better applied in building and working a certain number of screw-colliers, making seven or eight knots an hour. Some engineers contend that, at the average rate of freights, wages, and provisions, screw-colliers must be more profitable than the use of an immense ship, in which the coal occupies useful space which could otherwise be available for cargo. The approaching completion of the *Great Eastern* (August, 1859) will doubtless prepare the way for the collection of valuable information on this important question.

Since 1854 the use of screw-colliers has been adopted, not only on the Tyne and Thames route, but in other directions. In 1857 one was built to carry coals from Cardiff to London; it could take 1500 tons, exclusive of 150 tons to use as fuel. The hull was of iron, and there were arrangements for carrying 400 tons of water-ballast in the bottom, which could be readily pumped out when the ship arrived back at Cardiff. The ship cost 23,000*l.*, and the intention and hope of its owners were, that it would enable them to underbid the South Wales and Great Western railways in bringing Cardiff coals to London.

Concerning the actual cost at which coals can be placed on a railway from pits not far distant, an interesting calculation was made early in 1859, relating to some collieries in the Forest of Dean. It was estimated, that of 250 tons placed on the Great Western Railway, 95 tons of block coal could be delivered there at 8*s.* per ton, 70 tons of rubble coal at 6*s.* 6*d.*, and 85 tons of lime-coal at 2*s.*, being 69*l.* 5*s.* in all. The total cost was 45*l.* 6*s.* 3*d.*, or 3*s.* 7½*d.* per ton, thus made up:—

	s.	d.
Cutting the coal in the mine	2	0 per ton
Loading and rolling to pit's bottom	0	1
Pit-work, with timber and stone	0	3
Tram-plates and iron-work	0	2
Rope, tar, oil, and engine expenses	0	1
Breaking and hitching	0	2
Royalty or Rent to the Crown	0	2
Management	0	1
Conveyance on tram to Great Western Railway	0	4
Loading in railway trucks	0	2
Wear and tear of trams and machinery	0	0½
Incidental expenses	0	1
	3	7½

The cost to the consumer, beyond the price of 8*s.* per ton for block coal, would depend on the railway charges and the dealers' profits.

One or two other interesting matters concerning the coal trade of the metropolis may here be mentioned. Between the years 1807 and 1831 the corporation of London were owners of a Coal Exchange, kept up for their own profit; but in the last-named year an Act of Parliament converted the Coal Exchange into an open coal market, to be governed on certain regulations. The same Act defined the privileges of the corporation in certain matters relating to the coal trade; and most of these privileges were further sanctioned by subsequent statutes. A new Coal Exchange was built in 1849, under arrangements very convenient for sellers, buyers, and factors. The "whipping" of coals is a strange part of the coal-trade. The coal-whippers are labouring men, who "whip" or transfer the coals from the collier-brigs to barges, which barges generally carry them to wharves at the river side. The work is simply shovelling and hauling; but the men, several years ago, fell into the hands of publicans and others, who acted as middlemen, contracting with a captain or coal-owner to whip a ship of coals at a certain price, and then employing the men at a smaller price. By a kind of tally system, the men were drawn in to spend nearly all their earnings at shops belonging to the middlemen, for inferior goods supplied at high prices. The legislature has attempted to remedy this evil, but without much success; for if the men are not free agents in their dealings, the law cannot make them so. In 1851 Messrs. Prior introduced a mode of whipping coals by steam-power, and such will probably be the general mode after a time; but hitherto the hand method has prevailed.

COBALT (Co). One of the metallic elements. It does not occur naturally in the free state, but usually combined with arsenic, forming arsenide of cobalt (CoAs). In mineralogy this ore is known under the names of *speiss cobalt*, *tin-white cobalt*, or *smaltine*. Cobalt is also not unfrequently found as *cobalt-glance*, or *bright white cobalt*, a combination of arsenide and sulphide of the metal (CoS₂, CoAs). Other ores of cobalt have already been described, and their composition detailed. [COBALT, NAT. HIST. DIV.]

Metallic cobalt may, by somewhat tedious processes, be obtained from its ores. On account of the difficulties attending its reduction its properties have not been very thoroughly investigated, and consequently it has not yet received any application in the arts. For experimental purposes it may be prepared from the oxalate. The latter placed in a porcelain crucible, enclosed in a very refractory earthen one, and heated in a powerful wind furnace, will usually yield a button of the pure metal.

Cobalt is hard, brittle, and almost as infusible as iron. Its colour is reddish grey; it is magnetic, and has a specific gravity of about 8.9. It is soluble in dilute sulphuric or hydrochloric acids, with evolution of hydrogen. It tarnishes when exposed to the air, and is rapidly oxidised by nitric acid.

Equivalent of cobalt, 29.5.

The compounds of cobalt are remarkable for the beauty of their colour, and on this account have been used from the time of the ancient Greeks to the present day.

Zaffre is the name given to the compound of cobalt that occurs in commerce. It is a very impure oxide of the metal, and is produced by roasting the crushed selected ore on the sole of a reverberatory furnace, the sulphur burns to sulphurous acid, and passes off as gas, while the arsenic, oxidised to arsenious acid, is volatilised, and condenses in the long horizontal flues. The ore is finally ground to fine powder with two or three parts of pure siliceous sand. The product thus obtained is largely used in the manufacture of stained glass, principally to give the well known rich blue colour; it is also extensively employed in the ornamenting of pottery ware.

Smalt is a very finely ground deep blue glass, manufactured chiefly in Saxony. For this purpose the cobalt ore is only partially roasted, the object being to oxidise the cobalt only; the product is then mixed with about an equal quantity of carbonate of potash and twice its weight of well ground calcined quartz, and the whole melted together in suitable pots by the heat of a powerful furnace. In a few hours the silica of the quartz, and the potash combine to form a liquid mass of silicate of potash in which the oxide of cobalt dissolves, while the sulphides and arsenides of nickel, bismuth, and other metals, sink to the bottom of the vessel, there fuse, and under the name of *speiss*, are afterwards made use of as a source of the metal nickel [NICKEL]. The clear blue glass, after being skimmed, is ladled out of the pots and poured into water, by which it is so suddenly cooled that it instantly splits up into innumerable fragments; it is further minutely divided by grinding with granite stones under water, and the particles separated into different degrees of fineness by elutriation. Smalt is principally used as a pigment by paper-stainers.

Cobalt and oxygen form two well-marked oxides, the *protoxide* (CoO) and the *sesquioxide* (Co₂O₃). Some unimportant intermediate oxides also exist.

Protoxide of cobalt (CoO), eq. 37.5. As this oxide is an important article of commerce, being used to a considerable extent for enamel painting, it is prepared on the large scale from *zaffre*. The *zaffre* is dissolved in nitric acid, the solution evaporated nearly to dryness, strained from the arsenious acid that deposits, diluted with water, and a current of sulphuretted hydrogen passed through the solution till the

sulphides of arsenic, copper, bismuth, and tin, are thoroughly precipitated. The filtered liquid is now boiled to expel excess of sulphuretted hydrogen, a little nitric acid introduced to peroxidise iron, and carbonate of soda added till the oxide of iron and carbonates of nickel and cobalt are all precipitated. The precipitate is now, after washing, digested in strong solution of oxalic acid and again well washed on a filter; in this way the soluble oxalate of iron is entirely removed. The oxalates of nickel and cobalt are finally dissolved in strong solution of ammonia, and the liquid exposed for several days, when the oxalate of nickel is deposited, oxalate of cobalt remains in solution, and on evaporating to dryness and heating in an open crucible, the pure oxides of cobalt are obtained.

Another process consists in adding one part of roasted cobalt ore by small portions at a time, to three parts of fused bisulphate of potash, and then increasing the heat till no more fumes are given off; in this way excess of bisulphate of potash is converted into neutral sulphate, sulphate of nickel is decomposed and arseniate of iron formed; the latter remains undissolved when the cooled broken up mass is digested in water. From the aqueous solution antimony, bismuth, or copper are precipitated by sulphuretted hydrogen and pure basic carbonate of cobalt precipitated by carbonate of potash.

Pure protoxide of cobalt may be obtained by washing, drying, and igniting the carbonate, or from the mixed oxides produced in the first process by solution in boiling hydrochloric, precipitation by carbonate of potash and reduction of the carbonate by heat as just described. It is an ash-gray powder that in contact with air gradually absorbs oxygen, becomes brown, and ultimately black: heat causes the same change but more rapidly.

Hydrated oxide of cobalt (CoO, HO) is a rose-coloured precipitate, formed when either of the fixed alkalies are added to a solution of a salt of cobalt: when first formed it is pale blue (a subsalt). It is soluble in ammonia and most ammoniacal salts.

Salts of the protoxide of cobalt are formed by dissolving the basic carbonate, already described, in acids.

Sulphate of cobalt ($\text{CoO}, \text{SO}_3 + 7 \text{ aq.}$) crystallises from a solution, concentrated by evaporation, in carmine-coloured oblique rhombic prisms.

Nitrate of cobalt ($\text{CoO}, \text{NO}_3 + 6 \text{ aq.}$) forms red deliquescent crystals. A solution of this is used in blowpipe operations. A small quantity of the substance under examination is moistened with the solution, and heated in the blowpipe flame in any convenient manner; a pink-coloured mass indicates the presence of magnesia; a green residue, zinc; and a blue, alumina.

Phosphate of cobalt ($3 \text{ CoO}, \text{PO}_3$) is precipitated in violet flakes when ordinary tribasic phosphate of soda is added to a soluble cobalt salt.

Carbonate of cobalt (CoO, CO_2) is formed by digesting the basic carbonate $3(\text{CoO}, \text{HO}) + 2(\text{CoO}, \text{CO}_2)$, described under oxide of cobalt, in an alkaline bicarbonate.

Chloride of cobalt (CoCl) is obtained in ruby-red octohedra, when a solution of the carbonate of cobalt in hydrochloric acid is evaporated. It does not deliquesce.

Sulphide of cobalt (CoS) is precipitated when sulphide of ammonium is added to a solution of a salt of cobalt. Two other sulphides also exist, *sesquisulphide* (Co_2S_3), and *bisulphide* (CoS_2), but they are comparatively unimportant.

Sesquioxide of cobalt (Co_2O_3) is a brownish black powder, formed on passing chlorine gas through a dilute solution of potash in which oxide of cobalt is suspended; or by adding solution of chloride of lime to moist hydrate of cobalt.

Salts of sesquioxide have not been obtained in a definite state.

Ammoniacal compounds of cobalt. According to M. Fremy, when an ammoniacal solution of oxide of cobalt is exposed to the air that the protoxide may, by absorbing oxygen, be converted into the sesquioxide, there are formed combinations of four, five, or six equivalents of ammonia with one equivalent of sesquioxide of cobalt. These bodies combine with acids to form salts, in which the power of the ammonia for saturating acids is not exerted in the slightest. On account of the difference in colour of their salts he has named the bases—

Fuscobaltia	$\text{Co}_2\text{O}_3, 4\text{NH}_3$ (brown)
Rosecobaltia	$\text{Co}_2\text{O}_3, 5\text{NH}_3$ (red)
Luteocobaltia	$\text{Co}_2\text{O}_3, 6\text{NH}_3$ (yellow)

Claudet's ammoniacal salt of nitrate of cobalt ($\text{Co}_2\text{O}_3, 5\text{NH}_3, 3\text{NO}_3$) is an example of a salt of rosecobaltia. For further information regarding these interesting compounds, see a paper by M. Fremy, in 'Ann. de Chimie,' III., xxxv. 257.

Thénard's blue is a pigment that owes its delicate pale blue colour to cobalt. It is prepared by adding phosphate of potash to nitrate of cobalt, and mixing the resulting precipitate with gelatinous alumina obtained from carbonate of soda and solution of alum; the whole is finally evaporated to dryness and exposed to a dull red heat.

Rinman's green is produced by adding carbonate of soda to mixed solutions of the sulphates of cobalt and zinc.

Sympathetic ink. A dilute solution of chloride of cobalt has such a pale pink tint that characters written on paper with it are, when dry, invisible. On gently heating, however, the anhydrous chloride is formed, and this has a sufficiently deep blue colour to render the writing perfectly legible. On exposure to air, the paper absorbs

moisture, and the figures or characters again become invisible. By mixing the cobalt solution with a small quantity of a zinc salt, letters, &c., may be described, that when heated appear of a red colour; or with a persalt of iron, a green colour; with copper, yellow.

The use of oxide of cobalt in the manufacture of porcelain, &c., has already been referred to. It is, however, well known, that from the difficulty of thoroughly disseminating the oxide, spots of a colour darker than the surrounding parts are apt to be formed. To obviate this, M. Carré, of Sèvres, recommends the substitution of oxide of cobalt by a solution of one of the salts of cobalt; the latter can be more easily mixed with the porcelain mass, or with greater facility applied to any desired portions.

A test for cobalt, in addition to the precipitation of the sulphide, oxide, carbonate, and phosphate, already described, consists in heating a fragment of the suspected substance with borax, supported on platinum wire in the blowpipe flame; if cobalt is present, the resulting bead has an intense blue colour.

Quantitative analysis of cobalt. Cobalt is always estimated in the metallic state. The oxide is first obtained by taking advantage of any of the processes already mentioned, and is then reduced in a current of dry hydrogen with the aid of heat, and finally weighed.

COBALT ORES. Cobalt is not found in the native state, and its ores, though not numerous, require a more minute examination than they have hitherto received. We shall notice those which are best known.

Bright white cobalt, or *white cobalt*, occurs crystalline and massive; the primary form is a cube, the planes of which are usually striated; colour silver-white; streak grayish-black; lustre metallic; hardness 5.5, yielding with difficulty to the knife, and not very frangible; specific gravity 6.3–6.5; fracture uneven; cleavage parallel to the faces of the cube; before the blowpipe on charcoal gives arsenical fumes; and tinges borax of a deep blue.

It is found in fine crystals at Tunaberg in Sweden, in Norway, Silesia, and Cornwall.

It is met with also amorphous, arborescent, botryoidal, and stactitic.

Analysis of the crystals from Tunaberg by

	Klaproth.	Stromeyer.
Cobalt	44	36.7
Arsenic	55	49.0
Sulphur	00.5	5.6
	99.5	97.8

Tin-white cobalt, or *hard white cobalt*, occurs massive and crystallised in cubes and octohedrons; colour tin-white, but sometimes externally tarnished; fracture fine-grained and uneven; lustre metallic; it yields with difficulty to the knife, and is hard and brittle; specific gravity variously stated, from 6.74 to 7.7; yields arsenical vapour when heated with the blowpipe, and tinges borax deep blue.

The massive is amorphous, arborescent, botryoidal, &c. The amorphous occurs in Cornwall, and the crystallised at Skutterud in Norway. Analysis of the crystals by Stromeyer:—

Cobalt	33.10
Arsenic	43.46
Iron	3.23
Sulphur	20.00
	99.79

Gray cobalt occurs massive and crystallised; primary form a cube; colour grayish tin-white; streak grayish black; lustre metallic; hardness 5.5; specific gravity 6.466; fracture uneven; cleavage indistinct.

The massive occurs amorphous and reticulated. It is found principally at Schneeberg in Saxony, and is used in the manufacture of smalt.

Earthy cobalt occurs massive, amorphous, botryoidal, pulverulent, &c.; colour yellowish-brown and bluish-black; specific gravity 2–2.4; the fracture of the massive is earthy and dull, but polished by friction, and yields to the knife readily; when heated on charcoal gives an arsenical odour, and a deep-blue colour with borax. It is found in Hesse, Saxony, Bohemia, and also in Cheshire and Cornwall.

Sulphide of cobalt occurs yellowish-white and steel-gray; streak gray; it is amorphous or botryoidal, and externally brilliant; fracture uneven. According to Hisinger it consists of

Cobalt	43.2
Copper	14.4
Iron	3.53
Sulphur	38.50
Earthy matter	3.3
	99.96

Arseniate of cobalt—*Cobalt bloom*—*Red cobalt*—occurs fibrous, massive, and crystallised; primary form an oblique rhombic prism; colour various shades of red passing into crimson; sometimes grayish; translucent, transparent; it is soft, light, and flexible; specific gravity 2.948; the massive variety amorphous, botryoidal: structure fibrous,

radiating; before the blowpipe emits arsenical odours, and tinges borax blue: it occurs in Saxony, Bohemia, Scotland, Cornwall, &c.

Analysis by Bucholz:—

Arsenic acid	37.9
Oxide of cobalt	39.2
Water	22.9

100

Sulphate of cobalt—*Red vitriol*—is of a pale rose-red colour, and occurs investing other minerals, in small masses and in stalactites; the masses are semi-transparent and crystalline; it is soluble in water, translucent; lustre vitreous, often dull externally. It occurs among the mining heaps near Hanau and in Salzburg.

COBALTICYANIDES. [CYANOGEN.]

COBALTOHYDROCYANIC ACID. [CYANOGEN.]

COCCINONIC ACID. An acid of unknown composition, formed by heating euxanthic acid with nitric acid. Its salts of the alkalis are scarlet.

COCCOGNIDIC ACID. An acid of unknown composition, said to exist in the seeds of the *Daphne Gnidium*.

COCCULIN. [PICROTOXIN.]

COCCULUS, a genus of menispermaceous plants, for the botanical descriptions of which see NAT. HIST. DIV., comprises among others the *Cocculus palmatus*, of which the root furnishes calumba, a tonic of considerable medical efficacy.

Calumba acts chiefly upon the mucous membrane of the stomach, and upon the secretion and quality of the bile. It is not however without power over the nervous system, as its efficacy in allaying the vomiting of pregnancy testifies. In diarrhoea, after proper evacuations, and in bilious vomiting, it is superior to all other medicines. The vomiting and nausea of the early months of pregnancy are much alleviated by it; while the want of appetite, accompanied with general debility, of feeble children, is often removed by calumba along with preparations of iron.

Dr. Percival states that infusion of calumba will remove the disagreeable odour of putrefying ox-gall. Calumba-root, consisting as it does of one-third starch, should be given chiefly in the form of infusion or of tincture. For the preparation of the former cold water alone should be used, as enjoined by the Edinburgh Pharmacopœia; this leaves the starch undissolved, and extracts only the valuable active principles. The infusion made with boiling water spoils more rapidly than probably any other vegetable infusion; muddiness, followed by mouldiness, taking place very soon, especially if the infusion be allowed to stand on the dregs. Such a fermentable fluid cannot be a proper thing to introduce into an irritable or weak stomach, for which calumba is best suited of all vegetable tonics. Infusion of calumba made with cold water, combined at the moment of using with seltzer-water, is an excellent means of quieting the stomach at the beginning of fevers or bilious attacks. This also restores the appetite frequently lost from over mental exertion, or in the dyspepsia of sedentary literary persons. The common effervescing mixture made with lemon-juice or citric acid and bicarbonate of potash may be substituted, but it is not so good as seltzer-water.

COCHENILLIN. [CARMINE.]

COCHINEAL. (French, *Cochenille*; German, *Koschenilje*; Dutch, *Conchenilje*; Italian, *Cocciniglia*; Spanish, *Cochinilla*, *Grana*; Portuguese, *Cochenilha*; Russia, *Konssenei*.) Referring to the NATURAL HISTORY Division for an account of the insect, we will here simply say a few words concerning the trade in this valuable dye-stuff. Previous to the revolt of the Spanish American provinces almost all the trade in cochineal with the different markets of Europe was carried on through Spain, and chiefly through Cadiz; but since that event, and the consequent removal of the shackles which restricted the trade of Mexico, it has taken a more natural course, and the markets of consumption are supplied with cochineal either direct from the places of production, or from neighbouring stations, to which the article has found its way in the natural course of commerce. Representing a considerable value in a small bulk, cochineal is frequently used, with great convenience to merchants, as a medium for making remittances, and hence the comparatively circuitous route by which the greater part of it reaches the places of ultimate consumption. The quantity imported into Great Britain in 1827, was about 320,000 lbs.; which rose to 418,000 lbs. in 1835. So rapid was the increase in the next twenty years, that the importation in 1856 amounted to 2,000,000 lbs.; and in 1857, to 2,500,000 lbs. About one-half the quantity is brought from Honduras. Much is re-exported from England; but the increase of the trade is mainly due to the extension of dyeing, calico-printing, and colour-making in England.

COCK, or STOP-COCK, a kind of valve contrived for the purpose of permitting or arresting at pleasure the flow of a liquid through a pipe. The contrivances adopted for this purpose are very various; but those in most common use consist of a short tube of brass, intersected by a nearly cylindrical plug, capable of being turned on its axis, and so perforated or cut, that, while in one position it completely prevents the passage of fluid through the pipe, it may be so turned as to permit the fluid to pass through it, and consequently to flow through the pipe as though there was no plug to intercept its progress. In addition to

the differences in the construction of the plug or valve itself, many varieties are required in the form and arrangement of cocks, to meet the various circumstances under which they are applied. Those which, under the name of *taps*, are employed for drawing off the contents of barrels, simply need to be driven into the holes provided for them, which, before the barrels are broached, are filled with corks to prevent the escape of their contents. This kind of cock, which has been selected for illustration in the following figures, usually terminates in a curved *nose*, or spout, from which the liquor may be conveniently received in a jug or other open vessel; but where it is desired to transfer the liquor from the cask immediately to bottles, the nose is prolonged into a long slender tube, which will enter the neck of a bottle, and obviate the necessity for a funnel. Other kinds of taps are adapted for insertion in metallic cisterns or boilers, or for soldering to the ends of leaden pipes. Fig. 1 represents, in section,

one of the most common kinds of cock or tap, constructed for insertion in a barrel, as represented by the dotted lines at *d*; *a* is the end driven into the barrel, and perforated with a number of small holes, through which the surrounding liquor passes into the interior of the cock, but which, by their minute size, prevent the entrance of foreign bodies which may be floating in it; *b* is the nose or spout through which, when the cock is opened, the liquor runs out into the vessel placed to receive it; *cc* is a nearly cylindrical plug, rather smaller at the lower than at the upper end, accurately turned, and ground into the opening formed through the cock to receive it, and having a vertical slit or passage formed transversely through its axis, which may, according to the position of the plug, either coincide with or be made to lie across and be totally disconnected from the tubular passage through the cock. This point is more fully explained by Figs. 2 and 3, which represent horizontal sections of the plug and its socket or barrel, Fig. 2 showing the plug in the position represented in Fig. 1, in which position it completely intercepts or closes the passage through the cock, and Fig. 3, the plug turned one quarter round, so as to cause its passage to coincide with that of the tube of the cock.

One of the first improvements on this contrivance which claims notice is that of securing the plug in its place by means of a screw in its lower end, instead of by riveting; by which arrangement the plug may be readily withdrawn for the purpose of cleansing the cock. Of the many improved cocks in which the common form of the plug is departed from, that represented in Fig. 4 is highly ingenious. In this

the horizontal tube or bore of the cock opens into a vertical cylindrical chamber or barrel which is lined with a hollow cylinder of cork, and within the cylinder of cork is another hollow cylinder of metal, which constitutes the moveable plug of the cock. Through one side of this hollow plug a circular hole is formed in such a way that in one position of the plug it will coincide with the horizontal passage of the cock, which is continued through the cork lining of the vertical chamber, and thereby allow the liquor to escape by the vertical nose or spout, while turning the plug half round the solid side of the plug is exposed to the passage of the cock, so as effectually to close it. Separate cuts are given to show the transverse section of the plug, Fig. 5 showing it in the same position as Fig. 4, so as to close the passage, and Fig. 6 representing it as turned round to open the passage. This cock is represented without the usual T-shaped handle, the top

of the plug being so formed as to be turned by a moveable key, which is inserted through a hole in the brass cap which is screwed on to the top of the vertical chamber of the cock.

In many cocks the principle of the revolving plug is altogether departed from. The simplest of these consists of a curved tube of which the end driven into the barrel is closed by a flat disc of metal, covered with a leather washer, which may either be drawn into close contact with the end of the pipe, or pushed back from it to allow the liquor to enter. A more complicated cock on this principle has the disc-valve applied to the lower end of a vertical pipe; but instead of working the valve by means of an internal rod, the screw of which must be exposed to the action of the liquor, has two screwed rods, outside the passage for the liquor, which are moved simultaneously by the application of a key of the ordinary kind. Another kind of cock, of which there are several varieties, has a solid conical valve, capable of being either pressed into its seat, which must be ground with great accuracy, or removed from it to allow the liquor to escape, by means of a screw.

In drawing off liquors from a close barrel it is necessary not only to open a passage by which the liquor may escape, but also to admit air to occupy the place of the liquor abstracted. This is commonly effected by means of a conical plug of wood called a vent-peg, which is inserted in a small hole in the upper part of the barrel, so as to prevent the access of air when it is not required, but which may be taken out while the liquor is being drawn off. A very convenient substitute for the common vent-peg, intended especially for small beer-barrels, is manufactured in brass. It consists of a small tube of brass, which is screwed into the peg-hole, closed by a valve which is kept in its place by a spring, but capable of being opened by pressing the finger on a small lever while the cock is open. Cocks have been contrived to avoid the necessity of using a vent-peg, by causing an entrance for air to be opened by the action of opening the cock; this is the meaning of the familiar advertisement "No vent-peg required," in reference to certain ale-barrels.

The common mode of securing liquor-taps from improper opening by the use of a moveable key in lieu of the fixed T-shaped handle, is very imperfect, owing to the facility with which a key of the kind usually employed is imitated, and the comparative ease with which the plug may be turned round without a key. This has led to many ingenious modes of locking the taps, but most of them are too expensive to be brought into ordinary use.

Some of the superior kinds of cocks are manufactured in fine brass, and others, intended for use with vinegar or other corrosive liquors, of a white alloy less liable to be injured by acids; but the greater part are formed of a peculiar alloy known by the name of *tap-metal*, made of brass and lead. Cocks are cast in moulds, with a core, the plug and the barrel being formed separately, and the vertical perforation in which the plug works is afterwards turned smooth by means of a quadrangular steel rinder. Cocks have been made of cast-iron, of porcelain, and of other materials. The *four-way cock* is an ingenious contrivance: it consists of a plug perforated with two distinct passages, and mounted in a barrel into which four separate pipes or channels open; and its object is to connect the four passages with each other in alternate couples, either by a continuous revolution upon its axis, or by an alternating motion

through one-fourth part of a revolution. Figs. 7 and 8, in which a four-way cock is represented in section in two different positions, will illustrate this action. In these diagrams, *a*, *b*, *c*, and *d* represent four pipes between which it is desired to establish a communication which shall afford the means of connecting at pleasure the pipes *a* and *b*, and *c* and *d*, or by a simple movement of the cock to disconnect these, and connect *a* and *d*, and *b* and *c*. This simple apparatus has been adopted by several of the inventors and improvers of the steam-engine, as a means of alternately admitting steam to and allowing it to escape from each end of the engine-cylinder. It has, however, been in great measure superseded by the slide-valve, in all the better kinds of steam-engines.

CODE, CODEX. Before the use of more convenient materials, wooden tablets were employed by the ancients for writing on. Such a written tablet was called *codex*, of which *codicillus* is a diminutive. (Seneca, 'De Brevit. Vitæ,' c. xiii.) First they wrote by making notches or indents in these tablets, but afterwards they covered them with wax, and used a style to write with. (T. Astle, 'On the Origin and Progress of Writing,' c. viii.)

The word *codex* itself, which is the same as *caudex*, originally signified the body or trunk of a tree; afterwards, by an extended use, it was applied to a collection of planks or beams forming a raft (Aulus

Gell. lib. x. c. 15); and then, by way of analogy, it came to mean a book or collection of tablets, or sheets of writing on skins of parchment. (D. 32, 52, pr.) Of its general significations, then, the following may be noticed:—1. It may denote any handwriting on parchment or paper. 2. The diminutive *codicilli*, in the plural, besides meaning small tablets of wax, memorandum books, letters, and diplomas, also stands in the law books for codicil to a will, or less solemn additions to a testament. [*CODICILLUS*.] 3. A collection of laws is also called *codex*, or *code* in modern languages, as in English and French. In this sense the word is now most commonly used. There are several kinds of codes. A code may be made by merely collecting and arranging in a chronological or systematical order the existing laws of a state, which have been made at various times by the sovereign power. Such a collection is either made by public authority, as was the case with the *Codex Theodosianus* [*THEODOSIAN CODE*] and *Codex Justinianus* [*JUSTINIAN CODE AND ROMAN LAW*], or by private individuals, as is the case with the *Codex Gregorianus* and *Hermogenianus*. The Germans call collections of old German laws, made in the middle ages, "*Rechtsbücher*" (books of rights). Very different from a mere compilation of existing laws is a code (in German *Gesetzbuch*, book of laws), by which the legislative power sets up a new system of laws. A mere arrangement and classification of existing laws is more properly called a Digest; if to this classification and arrangement selection be super-added, it would still be properly only a digest. That some such notion as this influenced Justinian in the choice of titles by which he distinguished his celebrated collections of laws and constitutions may be gathered from the words of the code. (See C. 1., 17, 3, 1.) A code, though it may adopt many existing laws and customs, is now generally used to express a complete new system, founded on new fundamental principles; such principles, for instance, as are set forth in Bentham's 'Leading Principles of a Constitutional Code for any State.' In England, for example, if it were proposed to make a code, it might be found useful or necessary to modify the law of tenures, or to abolish certain kinds of tenures, such as customary tenures; and also to provide positive rules for numerous cases that are still either totally unprovided for or left doubtful by conflicting decisions, or regarded as of little authority. (See 'Humphreys on Real Property,' part ii.)

CODEIA. [*OPIUM, ALKALOIDS OF.*]

CODEINE. [*OPIUM, ALKALOIDS OF.*]

CODELA, an alkali existing in *OPIUM*.

CODES, LES CINQ, is the name given to several compilations of laws, civil and criminal, made in France after the Revolution, and under Bonaparte's administration. They consist of the Code Civil, Code de Procédure Civile, Code de Commerce, Code d'Instruction Criminelle, and Code Pénal. To these has been added the Code Forestier, or regulations concerning the woods and forests, promulgated under Charles X. in 1827. Hence the whole collection is sometimes called "*Les Six Codes*." But even this number is not correct, as there are also a Code de la Conscription, and a Code Militaire, both published under Napoleon. These two last are treated under CONSCRIPTION and MUTINY ACT.

Civil Code.—Before the year 1789 France possessed no general code or body of laws recognised as authority throughout all parts of the country; for the ordonnances of the kings, like the old Roman constitutions, although published for the benefit of the whole kingdom, and obligatory throughout it from one end to the other, yet neither laid claim to the dignity of codes, nor were intended to supersede the ancient laws. Two rival systems of law divided the country: one, that of the old customary law, embracing the provinces in the North; the other, that of the Roman or written law, embracing the provinces in the South. Such a division as this, and such a separation of interests, were in themselves evils of no little magnitude; but when, in process of time, the number of different and opposing customs became very materially increased, another evil was added to that of conflicting laws and legal principles; namely, a natural and almost insurmountable obstacle to a national union. To remove this was the aim of more French kings than one, foremost of whom must be mentioned Louis XI., whose efforts at establishing a uniform system of laws were only stopped by his death. In Henry III.'s reign, the publication of a code known by the title of '*Basilique*,' and drawn up under the superintendence of the celebrated Brisson, was interrupted by the dagger of the assassin Clément; whilst the reigns of Louis XIII. and Louis XIV. were distinguished,—the first by the appearance of the Code Michaud in 1629, which shared the fate of its compiler, Michel de Marillac; the second by the publication of no less than ten ordinances, passed either for the express purpose of codifying the several portions of the existing French laws, or with the view of removing obsolete laws and obstructive customs. (See the '*Collection des Ordonnances du Louvre*,' published in 15 volumes between 1723 and 1840.)

But however eager in the cause of law reform, and however anxious for the codification of the laws, had these sovereigns been, it was not till the throne was overturned and the republic established on the ruins of the monarchy that the great task of forming a French code was commenced. The first step towards realising this dream of former rulers and legislators was taken in the year 1790, by the declaration announced in the 19th article of the 2nd title of the law on the subject of judicial organisation,—"*A general code shall be formed, consisting of laws simple, clear, and appropriate to the constitution;*" but the fury of

the internal factions, the cares of foreign war, and the frequent changes of rulers, prevented any calm deliberation on the subject during the first years of the revolution. After Bonaparte became first consul, he appointed, in 1800, a commission, consisting of Tronchet, president of the Court of Cassation, Bigot de Préaménieu, Portalis, and Malleville, to draw up a project of a civil code. The project was printed early in 1801, and copies were sent to the Court of Cassation and the Courts of Appeal for their observations and suggestions.

These observations and suggestions were likewise printed, and the whole was then laid before the section of legislation of the council of state, consisting of Boulay, Berlier, Emmery, Portalis, Roederer, Real, and Thibaudeau. Bonaparte himself, and Cambacérès, one of his colleagues in the consulship, took an active part in the debates. The various heads of the code were successively discussed in the presence of the members of the commission, after which they were laid before the tribunate, where some of the provisions met with considerable opposition. The code, however, passed at length both the tribunate and the legislative body, and was promulgated in 1804 as the civil law of France, "*Code Civil des Français*." Under the Empire its name was changed into that of *Code Napoléon*, by which it is still often designated, though it has now officially resumed its original title of *Code Civil*. This code affects to define the civil rights of Frenchmen, and their legal relations to each other, and to society at large. In its general arrangement and distribution it resembles the institutions of Justinian; like them, it has adopted the great distinction of laws concerning the person, and laws concerning property. It consists of a preliminary title or introduction on the subject of the publication, the effects and the application of laws in general; and of three books, divided into titles or heads, each of which is subdivided into chapters and sections. Book I., in eleven heads, treats of persons; specifies their civil rights; regulates the means by which their rights are certified; prescribes the mode of registering births, marriages, and deaths; defines the conditions constituting the legal domicile of each individual; and provides for cases of absence. It then treats of marriage as a civil contract, the forms required, the obligations resulting from it, and lastly, of separation and divorce. The articles concerning divorce, which gave rise to much debate and opposition at the time, have been repealed since the Restoration, by the law of the 8th of May, 1816, and separation alone is now allowed; but with respect to the articles comprised in the 6th title on the subject of divorce, the editors of '*Les Codes Français annotés*, 1850,' say that although undoubtedly divorce was abolished by the above law of 1816, yet from the want of any explanation accompanying that abolition, the result has been to introduce such disorder into this part of the Code, that it is very difficult to determine in any precise and satisfactory way what articles of this 6th title were intended to be preserved, and what have been actually destroyed; hence, as they point out, one consequence has been to enlarge the jurisdiction of the bench in these matters, to give the judges greater latitude in doubtful questions on this branch of the French law; and, it may be added, to inflict no little injury upon the system of codification by substituting for the *littera scripta* of the Code, the uncertain and varying opinions of the judge. The code proceeds to treat of the relations of father and son, of legitimate and natural children, of adoption and guardianship, and of paternal power. Under this last head the French code, without adopting the rigid principle of the old Roman law in its full extent, gives to a father the right of imprisoning his son, if he be less than 16 years of age, for a term not exceeding one month; but if he have attained the age of 16, then, between that time and the commencement of majority or emancipation, for a term not exceeding six months, by a petition to that effect, addressed to the president of the local court, who, after consulting with the king's attorney, may give the order of arrest without any other judicial forms being required; and may in the first case abridge the time of confinement required by the father. The remaining heads treat of minority, guardianship, and emancipation; majority, which is fixed for both sexes, at 21 years complete; of interdiction, and the council of trustees, called "judicial" advisers, appointed in certain cases to administer the property of a man who is incapable of doing it himself. Book II. treats of property and its various kinds and modifications. The 1st head draws the distinction between *meubles* and *immeubles*, or personal and real property; though these two words do not express, to an English lawyer, the distinction between *meubles* and *immeubles*. The 2nd defines the different rights of ownership. The 3rd treats of usufruct, use, and habitation. The 4th concerns rural servitudes, the *prædiorum servitutes* of the Roman law, excluding all former personal servitudes which were abrogated at the revolution. Book III. treats of the various modes by which property is legally acquired, such as inheritance, donation *inter vivos*, and wills or testaments. A father can dispose by testament of one-half of his property if he has but one legitimate child, of one-third only if he has two, and of one-fourth if he has three or more. The law then proceeds to treat of contracts or conventional obligations, specifying the modes of proving them by written documents, official or private, or by witness, or lastly by presumption; and after briefly explaining the subject of engagements arising without contract, it proceeds to the 5th head, which treats of the marriage contract, and the respective rights of husband and wife according to the various stipulations, either by community or separation of property, or by dowry. Next come the heads

of sales, exchanges, contracts of hire, partnerships, loans, deposits, and sequestration. The 12th head concerns aleatory contracts (including insurance, bottomry, loans, plays and wagers, and annuity contracts). The 13th, 14th, 15th, 16th, and 17th heads, treat of mandate, or procurations, suretyship, transactions, arrest of body and security, &c. The law treats next of power of attorney, of bail and security, and of amicable compromise. The 18th head concerns privileged creditors and mortgages. This subject is very elaborately treated, and has been much extolled as a very valuable part of the Civil Code, on account of the security which it gives to property by means of the public offices for registering mortgages, of which there is one in every district. The registration of mortgages has been adopted in most of the Italian states, and other countries besides France; but even this system is not considered perfect, because there is no obligation to register every sale or transmission of property, nor the servitudes affecting property, and because the French code admits of sales by private contract, and of mortgages in favour of minors or wives, even without registration. In this particular the Austrian code is considered superior, because it enforces the registration of every transmission of property, and of every burthen or servitude, on the book of census, or cadastro, for each district. Monsieur Anthoine de St. Joseph, in his very valuable work, '*Concordance entre les Codes Civil étrangers et Code Napoléon*,' has extracted from Dr. Schein's '*Treatise on Public Registers*,' the Austrian regulations on the subject, from which it appears that the intention aimed at in the establishment of public registration in Austria, is, as is stated in the text, to enforce the registration of all proprietary rights over immoveables, for which purpose there are five classes of public registers: 1. The principal book, containing a full description of the property, the owner's name, its estimated value, its incumbrances, burdens, mortgages, &c. 2. The book of documents, that is, of those documents on which the owner's title rests. 3. The book of debts. 4. The book of receipts and acquittals. 5. The urbarium, or book comprising a detailed statement of all the charges to which the estate is liable, certified by the owner's signature. The reader is referred to the preface of St. Joseph's '*Treatise*,' pp. 89, *et seq.*, and to the preface of Troplong's '*Droit Civil Expliqué*,' vol. i. of '*Privilèges et Hypothèques*,' for some very able and searching criticisms on this part of the French civil code. (See also Grenier, '*Traité des Hypothèques*, 1824: '*Introduction*.') The 19th head of the French civil code treats of expropriation or seizing, or selling off by execution; and the 20th, or last, of prescription.

Much has been written on the merits and defects of this celebrated code. In order to judge of its value, we ought to read the reports of the discussions in the council of state by the most distinguished jurists of France. (Locré, '*Esprit du Code Napoléon tiré de la discussion*,' 6 vols. 8vo, 1805; Malleville, '*Analyse raisonnée de la Discussion du Code Civil au Conseil d'Etat*,' 4 vols. 8vo, 1807; and Lermier, '*Introduction à l'histoire du Droit*,' &c. c. 20.) On the other side, several distinguished German jurists have pointed out its imperfections. (Savigny, '*On the Aptitude of our Age for Legislation*,' translated from the German by a barrister of Lincoln's Inn; Rehberg '*über den Code Napoleon*,' Hanover, 1814; Thibaut, Schmidt, &c.) With regard to the part which Bonaparte took in its discussion, not of course as a professional man, but as a quick-sighted observer and critic, a lively account is given in Thibaudeau's '*Mémoires sur le Consulat*,' in which his own original expressions are preserved. (See also Barrett, '*Translation of the Code Napoléon*,' vol. i., p. cccxxxviii. &c.; and Blaxland's '*Codex legum Anglicanarum*,' pp. 173, *et seq.*, where a very good sketch appears of Cambacérès' three projects, that of the legislative commission, and Napoleon's commission for a Code.)

Code de Procédure Civile.—The Code Civil having determined what was law, it remained to prescribe the forms of civil process and the practice and rules of the courts. The Code de Procédure is divided into two parts. The first part treats of the ordinary forms of procedure before the various tribunals, and contains five books, of which the 1st relates to justices of peace and their jurisdiction. There are about 2840 of these magistrates in France, who decide petty cases not exceeding 300 francs, and also act as conciliators between parties at variance, who are not allowed to plead before a court without having first appeared before the juge de paix. The 2nd, to the process before the tribunaux de première instance, which try civil cases without jury. There is one of these courts in every arrondissement. The 3rd, treats of appeals to the Cours Impériales, of which there are 27 established in the larger towns, each having several departments under its jurisdiction; these courts try cases by jury. The 4th, of various modes of attacking judgments. The 5th, of the execution of judgments. The second part treats, in three books, of the different forms of procedure in the several cases indicated; the 1st book discusses (*inter alia*) offers of payment on the debtor's part, and of 'consignation' or payments into court in satisfaction of a debt; separation between husband and wife; interdiction and cession of property by an insolvent debtor. Foreigners are excluded from the benefit of the *cessio bonorum*. The second passes to the subject of inheritance, the affixing of seals, taking inventories, &c. The last book treats of arbitration. The Code de Procédure was in great measure founded on, or rather is a modification of, the ordonnance of 1667 of Louis XIV., with considerable ameliorations. It was framed by a commission appointed in 1802, consisting of Treilhard, Try, Séguier, Berthereau, and Pigeau, then discussed in

the council of state and the tribunate, and lastly passed by the legislative body. It was put in force in January, 1807. "An orator of the government, using the licence of flattery, said in his report that the principal difficulties in definitively settling the code had been cleared up by the emperor himself, who had adapted the forms to the present wants of society. The fact is that Napoleon took no part in the discussion of this code, which was conducted during his journeys to Italy and to the camp of Boulogne, and during the campaign of Austerlitz. Besides, it was a dry and unattractive subject, very unlike that of the Civil Code, and the emperor finding himself a complete novice in it, gave it up entirely to professional lawyers. His general views would have been to simplify the forms, and to check the sources of chicanery, but he was not heeded. One of his ideas was that solicitors and counsellors should not be paid unless they gained the cause. The routine lawyers, however, had too much influence in the work." (Thibaudeau, 'Histoire de France sous Napoléon,' vol. v., pp. 124-5.) The government afterwards published a table of the expenses, duties, fees, &c., attending civil process. The table, which is given at the end of the collection of the codes, presents a formidable appearance by the multiplicity and minuteness of the charges which attend every step of legal proceedings. Indeed this is the principal reproach made against the Code de Procédure, the multiplicity of formalities, written acts, registrations, stamps, &c. Another objection is, that in actions in which the state is concerned, it has advantages over private parties. But the publicity of the discussions, the security to all civil proceedings by means of registration, the well-defined authority of the various courts, the independence of the judges, and the establishment of local courts all over the country, and above all the institution of the supreme Court of Cassation—these are essential and lasting advantages. For an excellent résumé and criticism of the Code de Procédure, the reader is referred to the 'Law Magazine, or Quarterly Review of Jurisprudence' (1829), p. 454, *et seq.*; and for a practical explanation of its different articles to 'Les Codes Français annotés' (Teulet, D'Anvilliers et Sulpicy), vol. 2.

The *Code de Commerce* was promulgated in January, 1808. Its principal elements were drawn from the two celebrated ordonnances of Louis XIV., for which France is indebted to the genius of Colbert; that of 1673 relating to land commerce, and that of 1680 to maritime. Next to the Civil Code, it is considered the best part of French legislation. The institution of the commercial tribunals has been of great advantage to France, and has been adopted in other countries. These courts, of which there are 213, consist of a president and two or more judges, all chosen by the merchants among themselves, and for a time; they are not paid, but the greffier or registrar receives a salary. The Code de Commerce consists of four books: the first treats of commerce in general, of the various descriptions of commercial men, of the keeping of books, of companies and partnerships, of brokers, commissionaires, carriers, &c.; the second treats of maritime commerce, shipping, insurances, &c.; the third concerns bankruptcies; and the fourth treats of the commercial tribunals, their jurisdiction and proceedings. Appeals for cases above 1000 francs lie to the cour impériale of the district. As the subject of French mercantile law generally has no small claim on the attention of the civilised world, more especially on that of our own merchants and lawyers, a reference to some of the leading French authorities on the Code de Commerce may not be without its use; of these, the treatises of Pardessus and Boulay-Paty, on commercial law ('Cours du droit Commercial'), deserve the first place from the reputation of the authors, and the extent of the subject discussed in their pages. On the code itself M. Isidore Alauzet has published a commentary ('Commentaire du Code de Commerce'), in which each article is discussed and illustrated separately. M. Delangle has selected the third title of the 1st book, for a learned explanation of mercantile partnerships; whilst the well-known treatise of Mons. Locré, 'Esprit du Code de Commerce,' exhausts the subject as it was known to the public of 1811. Two English treatises of recent date ought not to be passed over, Mr. Leoni Levy's work on 'Commercial Law,' and a very useful little treatise called 'The Mercantile and Bankrupt Law of France,' by Henry Davies and Emile Laurent.

Code d'Instruction Criminelle.—The criminal laws of France under the old monarchy were defective, confused, and arbitrary. There was no penal code, but there were various ordonnances for the punishment of particular offences. The ordinance of Louis XIV. for regulating proceedings in criminal cases, introduced something like uniformity, but it maintained torture, which in some cases was repeated, secret trial, and other anomalies of the legislation of the middle ages. Torture was abolished by Louis XVI. The first National Assembly in 1791 recast the criminal legislation, introduced the jury, and remodelled the criminal courts after those of England. Then came the reign of terror, with its exceptional laws, or rather no laws at all but the caprice of the ruling faction. Bonaparte, when first consul, appointed a commission, consisting of Viellard, Target, Oudard, Treilhard, and Blondel, to frame a project for a criminal code. The fundamental laws were laid down in 1801, and were then discussed in the council of state. Bonaparte took a lively part in these first discussions, especially on the question of the institution of the jury, which he strongly opposed on the ground of the probable incapacity or party spirit of jurors: he looked upon the question in a political rather than a judicial light. Portalis, Simeon, Bigot de Préameneu, and Ségur sided with Bonaparte.

Treilhard, Berlier, Defermon, Crétet, Béranger, Merlin, and Louis Bonaparte defended the jury. There is an interesting account of this discussion in Thibaudeau (vol. vii. p. 88, &c.); and in 'L'Encyclopédie du droit' (1845), tom. iv. art. Codes Français, pp. 377-78. The question being put to the vote, the majority was favourable to the jury. The matter, however, was finally settled by suppressing the jury d'accusation, or grand jury, and retaining the jury de jugement. The jurors are taken from the electors who are qualified to vote for a member of the legislature, graduates in law, medicine, and other sciences, notaries, &c., and must be 30 years of age, and in the full enjoyment of all political and civil rights. A list of persons so qualified is made out by the prefect of the department, from which the President of the Cour Impériale, or of the Cour d'Assise, selects the number required to serve. The proceedings in criminal trials are partly written and partly oral. The accused is first brought before the procureur (attorney-general), who examines him and simply reports the case to the juge d'instruction, without giving any opinion upon it. At the same time, if the accused is charged with a crime punishable with personal and degrading penalties, he orders his detention. For mere délits or misdemeanours, bail is allowed. The juge d'instruction summons and examines the witnesses, and then sends back the report to the procureur, who makes his remarks on the case, which is then laid before the chambre de conseil, consisting of three judges of the tribunal de première instance. These judges investigate the case minutely, and decide if there is ground for further proceedings. In such case the report is laid before the chambre d'accusation, composed of five judges of the Cour Impériale, who ultimately decide for commitment or acquittal. If committed for a crime punishable by peines afflictives or infamantes, the prisoner takes his trial before the next cour d'assise of the department. If for mere délit or misdemeanour, he is sent before the correctional tribunal. The courts of assize consist of a president and three judges, chosen from among the members of the Cour Impériale and of the tribunal de première instance, and their sessions are held every three months in the chief lieu of each department. The jury decide by a majority on the fact of the charge; eight constitute a majority. The court then awards the sentence, having a discretion between a maximum and a minimum penalty. By a law passed since 1830 the court can no longer reconsider the verdict of the jury, as was the case before. The prisoner, or his counsel for him, may challenge the jurors as they are called peremptorily, but as soon as all the list of jurors, save twelve, is gone through, the challenges, whether on the part of the accused or the prosecution, cease. One or two juges d'instruction are attached to each court of assize for criminal cases; they are generally taken from among the juges de première instance, and for a definite time only. The Code d'Instruction Criminelle consists of the following books: 1. Of the judiciary police and the various officers whose duty it is to inquire after offences, collect the evidence, and deliver the prisoners to the proper courts. These officers are very numerous, including the maires and their assistants, the commissaries of police, the rural guards and forest-keepers, the justices of the peace, the procureurs and their substitutes, the juges d'instruction, &c. It also treats of the manner of proceeding by the procureur as already stated, and of the juge d'instruction and his functions, distinguishing between cases of flagrant crime and others. Book 2 treats of the various courts; tribunaux de simple police, which take cognisance of petty offences, and can inflict imprisonment of not more than five days, and a fine not exceeding fifteen francs; tribunaux en matière correctionnelle, which are composed of at least three judges of the tribunaux de première instance, and take cognisance of délits or misdemeanours, the penalties for which are defined in the Code Pénal; cours d'assise, already mentioned, from which there is an appeal for informality or want of jurisdiction to the Court of Cassation; lastly, the cours spéciales or exceptional courts, which Napoleon insisted upon having at his disposal, and which have been resorted to repeatedly since the Restoration, and still appear on the code. These special courts are assembled in cases of armed rebellion against the authorities, but they also take cognisance of the offence of coining and of crimes committed by vagabonds and convicts who have escaped; they are composed of a president taken from among the judges of the Cour Impériale, four judges, and three military officers of the rank of captain or above. They try without jury, judge by majority and without appeal, and the sentence is executed within twenty-four hours. On the subject of the Code d'Instruction, Thibaudeau observes that it retained many of the ameliorations introduced by the National Assembly, especially the publicity of trial and the institution of the jury. Its chief faults are, the great number of officers, some of them merely administrative, who are charged with the pursuit of offenders, by which circumstance the citizens are often exposed to vexatious interference; the too great extent given to the jurisdiction of the correctional courts, by which, in many cases, the citizens are deprived of the guarantee afforded by the jury; the restrictions on the choice of jurors, which is too much in the power of prefects and other local authorities; the institution of the special courts; and, lastly, the frequent abuse of the power of the police, by which its agents could issue warrants of arrest.

"Prefects and commissary-generals of police often had individuals arrested, and left them in prison waiting for the decision of the minister of police, who answered at his leisure, or at times confirmed

the order of arrest for an indefinite time. And as by Art. 75 of the Consular Constitution of the year 8, any suit against the agents of government was forbidden without an authorisation from the council of state, there was in fact no redress against arbitrary acts." ('Hist. de France sous Napoléon,' vol. vii. pp. 124-9.)

This last abuse is now corrected, or at least greatly mitigated. Other provisions of the Code d'Instruction, as well as of the Penal Code, have been also altered for the better by the law of 28 April, 1832, entitled 'Modifications aux Codes d'Instruction Criminelle et Pénal,' which is found at the end of the later collections of the French codes.

The *Code Pénal*, or laws defining crimes and punishments, was completed in January, 1810. Its discussion occupied forty-one sittings of the council of state. Of these sittings Napoleon attended only one (21 January, 1809); Cambacérès presided at all the rest. "Napoleon was therefore a stranger to its discussions; he only expressed an opinion that the laws ought to be concise, and leave much latitude to the judges and the government in the application of the penalty, 'because,' said he, 'men had feelings of compassion unknown to the law.'" He insisted upon the penalty of confiscation being retained in certain cases, because most nations had sanctioned it in cases of conspiracy, rebellion, and false coining. "But the definition of crimes and offences, the nature of the penalties, and the mode of their application, were the work of criminal jurists, who were generally inclined to severity, and were well acquainted with the ideas of Napoleon, who was persuaded that criminal legislation ought to be very rigorous in order to maintain order and support the authority of the government." (Thibaudeau, vol. viii. p. 3.) Hence the penalty of death was fixed in numerous cases, and those of perpetual imprisonment, hard work, or transportation for life, in a still greater number. The pillory is also one of the punishments.

If we look at book iii. ch. 1, which treats of the crimes and offences against the safety of the state (a term susceptible of indefinite and arbitrary application), we find that the penalties of death and confiscation are fixed very generally. Confiscation however has been solemnly abolished by a law passed under Louis XVIII. By the head, "Des critiques, censures ou provocations contre l'autorité publique dans un discours pastoral," any clergyman found guilty of having, in a pastoral charge, sermon, or other public address, spoken or printed, criticised or censured any act of the government authorities, is subject to banishment, transportation, or even death, according to the consequences which have resulted from his act. The following head, "Résistance, désobéissance, et autres manquemens envers l'autorité publique," is equally severe. The article "Délits commis par la voie d'écrits, images ou gravures, distribués sans nom de l'auteur," &c., concerns the press, which was under a strict censorship in Napoleon's time. After the Restoration the censorship was abolished, and several laws were enacted to repress abuses of the press, especially in April and October, 1831. An important law on this subject was promulgated in September, 1835, consisting of five heads: 1. Crimes, délits et contraventions. 2. Du gérant (editor) des journaux ou écrits périodiques. 3. Des desseins, gravures, lithographies, et emblèmes. 4. Des théâtres, et pièces de théâtre. 5. De la poursuite et du jugement. It is printed at the end of a collection of codes, laws, &c., published in 1835, and styled 'Les dix-huit Codes du Royaume.' The last general law relating to the press was published on the 16th of February, 1852, which contains some very stringent provisions, by which, among other things, it is enacted that no journal or periodical relating to political subjects or *social economy* shall be started or published without the authorisation of the government; that no foreign journals on the same subjects shall circulate in France without the same authorisation; that all proprietors of such journals whose publication is allowed must deposit with the Treasury a certain sum in cash by way of caution money; and that for infringements of these rules the punishment shall be imprisonment varying from one month to a year, and a fine ranging from 100 fr. to 5000 fr. in each case. In addition to these regulations, a stamp duty is imposed upon all journals or periodical publications; punishments by imprisonment and fine are decreed for the publication of false news and fabricated documents. Unauthorised accounts of the sitting of the senate, and *all reports of trials for press offences* (which are merely to be mentioned) are interdicted; and all gérants, or managers of newspapers, are compelled to insert at the head of their journals any official documents, of whatsoever kind, that may be addressed to them by any public authority. The 32nd article specifies the regulations on the subject of the official condemnation of a journal for contraventions or offences of the press, one short extract from which will give the reader a specimen of the spirit of the whole law itself: "A journal may be suspended by ministerial decision even when it has not been the subject of any condemnation, after two formal notifications, and during a period which cannot exceed two months." By the section of the Penal Code entitled 'Des Associations ou Réunions illicites,' which continues in force to this day, every association of more than twenty persons for the purpose of meeting on fixed days to discuss either political, religious, literary, or other subjects, is declared illegal, unless it first obtain the approbation of the government, which can prescribe conditions and fix regulations at its pleasure. The chiefs or directors of any such illegal association are punished by fine. If at the meetings of such assemblies there has

been any provocation to crimes or délits, as defined in the other articles of the penal code, the chiefs or directors and administrators are liable to imprisonment from three months to two years, besides fine, although they themselves may not have been guilty of the offence. No individual can lend his house or apartments for the meeting even of an authorised association, unless he first obtain the permission of the municipal authorities. By a law which passed the Chambers in April, 1834, the above regulations have been made even more strict. Every member of an illegal association is liable to a fine of 1000 francs, and to imprisonment from two months to one year. For the existing regulations on the subject, as comprised in the Code Pénal and the law of 1834, the reader is referred to the second volume of 'Les Codes Français Annotés' (edition 1850). Under the heads "Vagabondage" and "Mendicité," vagrants are defined to be all those who have no fixed domicile, nor means of subsistence, and who do not follow habitually any trade or profession. On the legal evidence of being such, they are condemned to an imprisonment of from three to six months, after which they are "at the disposal of government." With regard to mendicants or beggars, any person found begging in a place where there is a workhouse or dépôt for the poor is subject to from three to six months' imprisonment. But the next article is much more liable to objection on the score of justice and humanity; it runs thus: In places and cantons where there is no dépôt for the poor (which is the case in most rural districts of France), able-bodied beggars shall be imprisoned for a period of from one to three months; and if arrested out of the canton where they reside, they are imprisoned for a term of from six months to two years. By Article 402, bankrupts not fraudulent are liable to imprisonment from one month to two years. Brokers in the same situation are condemned to hard work for a time.

The law of France makes a wide distinction between native and foreign insolvents in two important points: first, in the preliminary proceedings of a suit, both as regards the person and the goods and chattels of the foreigner; and secondly, as regards the term of imprisonment. For, as respects the first of these points, "when a French subject claims a debt, no matter of what amount, of an alien, and produces in support of his claim written evidence, either of a nature held to be conclusive, or of a character to raise a strong presumption in favour of the claim, the French Tribunal *will, upon application, grant a warrant of apprehension* against the person of the alleged alien debtor, unless the latter has an establishment in France. The court will also, under the same circumstances, grant the claimant authority to seize and hold in pledge, for his protection, the goods and chattels of his alleged alien debtor." ('The Mercantile and Banking Law of France,' p. 2; Davies and Laurent.) While, with regard to the second, foreigners not domiciled in France, having no commercial establishment or real property there, are liable to double the period of imprisonment that a Frenchman is, namely, two years for a debt less than 500 francs; four years for a higher sum under 1000 francs; six under 3000; eight for less than 5000; and ten years for 5000 and upwards. (Okey, 'Concise Digest of the Law, Usage, and Custom affecting the Commercial and Civil Intercourse of the Subjects of Great Britain and France.') By the head 'Violations des réglemens relatifs aux manufactures, au commerce, et aux arts,' any coalition between masters to lower wages is punished by a fine of from 200 to 3000 francs, besides imprisonment not exceeding a month. Coalition among workmen, followed by an attempt to stop the works of a manufactory, is punished by imprisonment of from one to three months; the leaders or originators of the coalition or attempt are subject to imprisonment from two to five years. By Article 417, any one who, with the view of injuring French industry, has removed to a foreign country the workmen or clerks of a manufactory, may be imprisoned from six months to two years, besides paying a fine of from 50 to 300 francs. Article 418: Any director, clerk, agent, or workman, of a manufactory, who communicates to foreigners or to Frenchmen residing abroad, any secret of the fabric in which he is employed, is punished by a fine of from 500 to 20,000 francs, besides imprisonment at the discretion of the court. Article 421: All wagers or bets upon the rise or fall of the public funds are punishable by imprisonment from one month to one year, besides a fine of from 500 to 10,000 francs. The offenders may, after the expiration of their imprisonment, be placed by sentence of the court under the surveillance of the haute police from two to five years. This sentence, "placed under the surveillance of the high or government police," which is added at the end of numerous penalties, means that the person so placed is to give security for his good conduct; in default of which he is "at the disposal of government," who may fix a particular place for his residence. All individuals who have undergone the punishment of hard work for a time, or that of banishment or transportation, or those who have suffered a penalty for political crimes, are placed, *de jure*, under the surveillance of the high police for the rest of their lives.

The above extracts are sufficient to show the spirit in which the French criminal code has been framed. It is, in fact, as harsh and illiberal in many of its enactments as that of any absolute government in Europe. In speaking, therefore, of Napoleon's legislation, it is necessary to discriminate between the civil and the criminal laws; and again between the laws themselves and the practice and rules of proceeding in the courts. The adoption of the French criminal code met

with great opposition in Italy. At Milan the legislative body attempted to modify and adapt it to the habits and wants of the Italians. Two commissions were appointed by the minister of justice, one for the Code d'Instruction and the other for the Code Pénal. Their reports were sent to Paris, but were rejected by Napoleon, and an answer came with peremptory orders to translate literally, and enforce the two French codes without any alteration. At Naples similar objections were also made, but with no better effect. (Colletta, 'Storia del Reame di Napoli,' book vi.)

For comments and strictures by French jurists on the criminal laws of France, see Béranger, 'De la Justice Criminelle en France,' 1818; Dupin, 'Observations sur plusieurs points importants de notre Législation Criminelle;' and Bavoux, 'Leçons préliminaires sur le Code Pénal,' 1821; Bourignon, 'Jurisprudence des Codes Criminels' (Préface), 1825; 'Encyclopédie du Droit' (1845), Art. 5, p. 374; and for a comparison of the French and English systems of criminal law, see Cotton, 'De l'Administration de la Justice Criminelle en Angleterre, et de l'esprit du Gouvernement Anglais.'

There are in France more than 3000 judges, including those of the commercial courts, besides 2840 juges de paix. The judges of the Tribunaux de Première Instance have salaries varying from 2000 to 6000 francs; those of the Cours Impériales, from 8000 to 8000. The presidents and vice-presidents receive more in proportion. The juges de paix receive about 800 francs, besides certain fees. The various courts, magistrates, greffiers, &c., cost the state about fifteen millions of francs annually. (Goldsmith, 'Statistics of France,' 1832.)

For a general view of the judiciary system of France, see Meyer, 'Esprit des Institutions Judiciaires,' last vol.; and Rey, 'Des Institutions Judiciaires de l'Angleterre comparées avec celles de France et de quelques autres Etats,' 1826.

CODICIL. [WILL.]

CODICILLUS, the diminutive of Codex, signifies properly a small trunk or stump of a tree (*parvus codex*), but in process of time the word had, like Codex itself, various meanings given it, more especially in the plural, when it came to signify little tablets smeared over with wax, and marked or written on with a stylus. To the constant use of these among the ancients before the discovery of paper or the application of the papyrus, Pliny bears witness in two passages of the 'Natural History,' in each of which he uses the word codicillus. ('Nat. Hist.' l. 13, c. 13; and l. 33, c. 4.) But after the invention of another material for writing on, another meaning was given to the word codicilli, namely, that of memorandum, or note-book, in which entries were hastily jotted down for the purpose of being copied in extenso on charta or paper. (Cic. 'Philip' 8, c. last but one; 'Fam. Ep.' l. 9, ep. ult.) Not that this was the sole meaning of the expression, for we find Cicero and Seneca using it in the sense of letters, especially those intended for neighbours and intimate friends. (Cic. 'Fam. Ep.' 6, 18; Seneca, 'Ep.' 55 *in fine*.) From this confined signification it was extended to that of a book, treatise, or writing (Tac. 'Ann.' 11, 34); to that of a memorial and petition (Tac. 'Ann.' 4, 39; 69); to that of a letter conferring privileges, in which sense it is found in the Cod. Theodos. tit. 4, l. 23; and lastly, as a technical legal term to that of letters addressed by a testator to the heir or heirs named in his will, as to certain things which the testator wished to be done by his heir or heirs after his decease. (Heinecc., 'Antiq.' ii., tit. xxiii. and xxv., sect. xi.)

The difficulty which existed, out of Rome, of procuring the legal number of Roman citizens as witnesses to a solemn will, led to the use of codicils. The story of their invention and progress in the jurisprudence of Rome is told very graphically in the 'Institutes' (ii. 25), from which it appears that Lucius Lentulus, just before his death in Africa, had appended some codicillary memoranda to his will, addressed to Augustus, and in them had requested the emperor to do some act for him by way of a *fidei commissum*. These instructions were obeyed by the emperor, as well as by sundry other individuals who seem to have received similar requests, whereupon Lentulus's daughter, probably out of reverence for her father's memory, took upon herself to pay certain legacies, which could not have been legally obtained by the legatees. The emperor, it is then stated, influenced perhaps by the novelty no less than the advantages of this addition to the testamentary powers of a citizen, summoned the leading lawyers of the day, and on their authority, backed by that of Trebatius, gave his formal assent to the introduction of these codicilli. From that time codicils became legal instruments.

Codicilli have been defined to be supplements or additions to a testament, which are to be considered as annexed to the will itself, for the purpose of adding, explaining, or altering something in the previous disposition. But such a definition does not give an exact notion of the term; and, besides this, it applies only to the cases where the person making the codicil dies testate; consequently it does not take in those cases where no will exists. More correctly, codicil is defined to be a less solemn will, in which, as well as in a solemn will or testament, every disposition that can be effected by a last will may be made, except the appointment of direct heirs and exheredation; that is, the disinheriting of sons, daughters, &c. Codicils were commonly used for the purpose of naming bequests or legacies to be paid by the heirs already appointed by a testament, and for explaining and clearing up obscurities and want of precision in a testament.

There are two species of Roman codicils: *ab intestato*, when a man

who made a codicil died intestate; and *codicilli ad testamentum facti* when he died testate. In the former case the dispositions in the codicil had reference to the heres ab intestato, or the person to whom the law gave the intestate's property. Codicils of the second species were either confirmed by the testament (*codicilli confirmati*) or not (*non confirmati*). Before Justinian's time there were several differences between these two sorts of codicils, particularly as to legata and fidei commissa; but the different species of bequests being put on the same footing in the reign of Justinian, the distinctions ceased. In the time of Pliny the Younger, a codicil made before a subsequent will ought to be confirmed by the will (lib. ii., Ep. 16); but this was afterwards dispensed with. ('Instit.' ii. 26.) Sometimes future codicils were confirmed by a prospective will.

Codicils might be written, in which case they were either public or private; or they might be verbal directions given to the heir. In their origin codicils had no particular forms, but the Emperor Constantine required witnesses to codicilli *ab intestato*, and to codicilli *non confirmati*; and Justinian required witnesses for all private codicilli.

A testament wanting the legal forms required for such a solemn instrument might be maintained as a codicil if the legal forms for a codicil were observed, and the will contained what is now termed codicil-clause (*clausula codicillaris*). (See Brissonius, 'De Formul.' lib. viii.; Gaius, lib. ii. 270, Dig. 29, tit. 7; and McKelvey, 'Systema Juris Romani,' § 700-704.)

CODIFICATION. [LAW AND LEGISLATION.]

CO-EFFICIENT (in Algebra). When two or more numbers are multiplied together, each of them is called a factor of the product, and a co-efficient (or co-factor, as it were) of the other factors. Thus the factors of the product $a \times b \times c$ are a , b , and c ; and a is the coefficient of $b \times c$, b of $a \times c$, and c of $a \times b$. But the word is most frequently used for that which should be distinguished as a numerical coefficient; thus in $2x \times 3y$, 2 and 3 are respectively the coefficients of x and y . This word is as old at least as the writings of Vieta, in which it has its present sense.

When there is a multiplier depending upon the result of experiment connected with any particular property of matter, the number is frequently called the coefficient of that property. Thus by the coefficient of friction for any substance, is meant the fraction of the pressure which is equivalent to the friction of that substance.

COEHORN, a small mortar for throwing grenades, invented by the engineer of that name.

COEMPTUS. [MARRIAGE.]

CENOBITES. [CONVENT.]

COFFEE—*Medical uses of*. The action of coffee on the human system is due chiefly to the empyreumatic oil, and consequently is greatest when roasted; but its extractive and also highly nitrogenous principle, *caffcina*, must exert considerable influence upon the organs of digestion.

Coffee acts powerfully and peculiarly on the ganglionic system of nerves and their ramifications, and all the organs which are supplied by them. It elevates the vitality of these nerves, and quickens all their actions. The brain is likewise markedly acted upon by it; and hence the increased sensibility and greater energy of that organ during the use of coffee, and the removal of all sense of fatigue or disposition to sleep. Upon this depends, in addition to its local influence upon the organs of digestion, the utility of coffee in counteracting the effects of narcotic poisons, such as opium or belladonna, and the favour it has found among literary persons from enabling them to carry on their studies through the midnight hour without feeling oppressed by sleepiness. It greatly promotes digestion if taken after dinner, and also checks the disturbance of the nervous system arising from the too free use of wine. It excites the vascular system, and renders more powerful the contractions of all the muscles, both voluntary and involuntary. It fits the system therefore to resist the influences of cold and damp, and is proper for night travellers and the inhabitants of humid climates, such as Holland. In warm climates it removes the languor which oppresses those who are exposed to the excessive heat, and helps the stomach to perform its office.

It is not without its counterbalancing disadvantages. For plethoric persons, and those who have a tendency to abdominal congestions, it is unsuited; and for persons subject to piles it is in general improper, as well as for females under certain states of their system. It is likewise hurtful to persons having a very excitable vascular system, being upon the whole more suitable for slender persons or those advanced in life, than for the young or very robust.

Coffee, like all stimulants, when used to an injurious extent, gives rise to disturbances of the nervous system, particularly painful twitchings of the upper eye-lid, to congestion or hæmorrhages, loss of digesting power, and obstruction of the liver and *vena porta*. Unlike the nervous symptoms caused by tea, the greatest number of these complaints subside or disappear on discontinuing the use of the strong beverage.

Coffee is much more extensively used as an article of diet than of medicine. Raw coffee, either in the form of powder or of infusion, has been found very serviceable in the cure of intermittent fevers. ('Edinburgh Medical and Surgical Journal,' No. lxii.) Raw coffee is more nutritious than roasted. A strong infusion of coffee without sugar or milk often removes megrim or hemicrania; and also in some

cases of asthma, either alone or with tincture of opium, it has kept off the paroxysm. Strong coffee is the best and safest means which can be employed by unprofessional persons to obviate the effects of all vegetable poisons which act upon the brain, and induce a fatal sleepiness and torpor. It is much more proper than vinegar which should never be given till all the poisonous substance has been removed from the stomach.

In some affections of the kidney and bladder, such as laxity and debility of these organs, coffee is of much service; and it has been stated by some writers that calculous complaints have diminished since its more extensive use.

Caffeina has not yet been used extensively in medicine, but Geiger justly anticipates that a principle so rich in nitrogen will be found to be an important medicinal agent. It is a powerful stimulant.

A beautiful green, which is unchangeable, and resists the action of acids, light, and moisture, may be precipitated from a decoction of decayed coffee, by means of pure soda. [CAFFEIC ACID.]

COFFEE TRADE. Referring to the NATURAL HISTORY DIVISION for an account of the botanical relations of the coffee-plant, and of the mode of preparing the bean or berry for the market, we shall here offer a few observations on the coffee-trade—not simply in its buying and selling, but also in relation to the apparatus for preparing it.

Coffee beans should not be roasted long before they are ground, nor long before they are to be made into a decoction; the retention of the aroma, and of all the good qualities in the coffee, depends on this. About half an ounce of coffee powder should be used for every eight ounces (half a pint) of water. In Britain the roasting is generally carried too far. It was an endeavour to establish an improved mode of roasting coffee that led to the death of Mr. Dakin, of St. Paul's Churchyard, in 1848. His plan consisted in placing the coffee in a cylinder lined with silver, and in enclosing this cylinder within a cellular steam oven, or cylinder, patented by other parties. The heat attained within the oven was very great, and the metal of the oven was not sound enough to resist its action: an explosion ensued, with a fatal result. The silver or silvered cylinder was an intended means of retaining the fine qualities of the coffee, without acquiring any defective qualities during the roasting.

Considerable ingenuity has been displayed in devising apparatus for preparing coffee for the table. The ordinary coffee pot is the plainest and simplest of all; there is no contrivance for filtering the coffee. In Dresden and other parts of Germany, a thick piece of flannel or some other woven material, is laid in a funnel; the ground coffee is placed on the flannel; and the boiling water filters through the coffee, the flannel, and the funnel, to a vessel below—carrying with it the flavour of the coffee without the grounds or sediment.

Platow's Automaton Coffee Pot has for its object to make coffee in less time and in a better manner than by the ordinary method. The machine consists of two parts. There is at the top a glass vase which screws off and on by means of wooden handles, and is furnished with a long narrow straight tube, resembling the pipe of a common funnel, and reaching nearly to the bottom of a metallic urn placed beneath the vase. Boiling water is poured into the vase in quantity sufficient for the coffee to be made; and this is allowed to descend into the urn. The ground coffee is then placed within the vase, on a small perforated silver plate. A lamp containing spirit or naphtha is placed beneath the urn; and in a short time the peculiar action of the apparatus develops itself. The steam formed on the surface of the water in the urn forces, by its elasticity, the water up the tube into the glass vase; where it acts upon the coffee in the usual way for extracting the qualities of the berry. When the coffee is so far prepared and is required to be *fined*, the lamp is removed, the formation of steam ceases, a partial vacuum is formed in the urn, and the external atmosphere, pressing on the open vase, presses or strains the coffee, first through the grounds and then through the perforated silver plate; so that it trickles into the urn in the state of a pure bright decoction. It is thus seen that the liquid makes two descents and one ascent between the vase and the urn, during the process. In a cheaper form of the apparatus, a common fire or a lamp is used instead of a spirit lamp.

A coffee-pot of rather complicated structure was patented by Mr. Andrews of Wolverhampton, in 1842. This coffee-pot had no less an adjunct than a small forcing-pump, placed near the handle. The boiling water was poured in the forcing-pump, while the ground coffee was put in a perforated vessel in the middle of the coffee-pot; and the hot water, being forced by the pump, was made to saturate the ground coffee in a way which (we presume) was supposed to produce a result adequate to the costliness of the apparatus.

Waller's Coffee Pot, patented in 1847, differs in many particulars from all the others. A horizontal partition, perforated near the centre with fine holes, divides the vessel into two equal chambers; an open pipe leads nearly from the top of the upper chamber to near the bottom of the lower chamber; and another pipe leads from the perforations some way down the lower chamber, with a tap or cock which can be worked by a handle protruding through the side of the coffee-pot. The requisite quantity of water, either hot or cold, is poured into the upper chamber, and allowed to flow through the perforations and small pipe into the lower chamber; the ground coffee is placed on the perforated plate; the spout is closed with a cork or plug; and the vessel is placed on the fire. As the water becomes heated, the steam

generated has no outlet upwards or sideways, and it therefore presses on the water, and forces it up the long pipe, whence it falls into the upper chamber, upon the ground coffee. When all the water is thus forced up, the coffee-pot is removed from the fire, the vacuum in the lower chamber is condensed, the plug is removed from the spout, the top of the short pipe is opened, and the water trickles through the ground coffee and through the perforations into the lower vessel, imbibing all the soluble and aromatic properties of the coffee as it descends.

Many other varieties of coffee apparatus have been invented within the last few years; but they need not be separately described here.

Attention has been directed within the last few years to the properties of coffee leaves, as a substitute for the berry. It has been ascertained, by a mercantile house at Singapore, that roasted coffee leaves could be there sold at twopence per pound; and in 1853 an attempt was made to introduce this article into the English market—hitherto without much success. An essence of coffee is made for keeping; it consists of a highly concentrated infusion, mixed to the thickness of treacle with chicory and burnt sugar, and kept cool in well corked bottles; it is used to make coffee beverage quickly under special circumstances, but it is not quite equal to fresh coffee. Coffee syrup is the essence combined with sugar and milk, and greatly evaporated; it becomes coffee paste, and then coffee candy, if the evaporation be still further continued.

Coffee is adulterated to an enormous extent, as sold in the retail shops. Chemists have detected, mixed up with it in various ways, the following substances—acorns, almonds, beans, beech-mast, beet-root, chick peas, currant seeds, chicory, gooseberry seeds, holly berries, lupins, rice, rye, sassafras, water flag seeds, and many others. The chief among these adulterants is chicory, which is often mixed in enormous quantity with cheap coffee. The best security against adulteration is perhaps to purchase the coffee unground.

We now present a few figures concerning the coffee trade.

It has been estimated that the quantity of coffee annually exported from the countries where it is grown cannot be less than 120,000 tons, or 2,400,000 cwt. Nearly all the coffee now consumed in Europe is the produce of trees propagated from a single seed, sent from Mocha to Batavia in 1698; the progeny of this first plant was sent to the West Indies in 1718; and thus the great coffee plantations began. The chief coffee growing countries are Ceylon, Brazil, Central America, Cuba, Hayti, Java, British West Indies, Guiana, French West Indies, Porto Rico, Sumatra, Isle of Bourbon, Manilla, and Mocha; these are enumerated nearly in the order of their importance. England purchases far less coffee than France, Germany, or the United States, in which countries coffee drinking is more prevalent. Our total imports, in certain years, were as follows:—

1845	50,000,000 lbs.
1850	51,000,000 „
1855	64,000,000 „
1858	61,000,000 „

This list does not denote the quantity of coffee *used* in the United Kingdom; for a greatly-fluctuating proportion is every year re-exported. The quantity retained for home consumption varies from 35,000,000 to 40,000,000 lbs. per annum. In 1844 the importations from British possessions were about equal to those from foreign possessions; but since that year the former have more and more predominated; until at length in 1858 the ratio was 51 millions of pounds British against 10 millions foreign. Variations in the import duty have had much to do with these fluctuations.

COFFER-DAM. A temporary enclosure around the position intended to receive the foundations of a structure to be built in water, so constructed as to allow the water to be pumped out of the space enclosed, and the building operations to be subsequently conducted “in the dry.” Cofferdams are used when the depth of water at the place under consideration is very great, and the importance of the structure or the nature of the subsoil, are such as to render it inexpedient to employ the diving-bell, or to resort to the use of caissons, or of concrete foundations within close-piled enclosures. [BRIDGE.] They may be, according to their depth, either simple banks of earth; or timber-walls backed with earth; or double linings of timber filled in with impermeable clay; or, finally, boxes or cases of wood, filled in as before with clay. The complication of the framing, or of the cross strutting of a coffer-dam, will, of course, depend on the effort to which it is to be exposed; and in deep tidal rivers these structures become very costly and important preliminary works in the erection of bridges, docks, wharves, &c.

The thickness of a coffer-dam, of whatsoever material it may be composed, is regulated by the consideration that it must be able not only to resist the dead action, so to speak, of the water to be excluded, but also its live action, or shock. It is customary, therefore, to make the thickness of simple earthen dams equal, on the average, to their height; and for this reason their use must be confined to such positions only as would allow so much room to be devoted to the purpose, and when the depth becomes at all considerable, the mixed systems of construction must be resorted to. In the case of a simple timber dam, backed with earth, the timber acts partly to resist the statical action of the water by means of its own transverse strength, and partly to

protect the earthwork from the effects of any current which may exist in the stream; but when a double enclosure is resorted to, it is frequently so strengthened by struts and cross-bracing, that the whole of the resistance to the water is obtained from them, whilst the earth contained within the enclosure only performs the function of excluding the passage of water from one side of the dam to the other. The simple dams backed with earth are often used to protect the foundations of abutment-walls of bridges, of wharves, &c., immediately connected with the shore; whilst the double enclosure is almost always adopted when the foundations of piers, or other works in deep, tidal streams, require to be executed with particular care. It is to be observed, also, that in the construction of coffer-dams the consideration of the lateral displacement, by reason of the tendency to slip upon the bed, is of less importance when timber enclosures are used, than it is in ordinary earth-work dams, because the hold of the piles in the ground enables them to resist that particular action; whereas the earthen dams only resist by the friction upon the surface of their bases.

Assuming that in either case (that is to say, whether timber or earth-work be used) there is no danger of lateral displacement of the dam, the pressure which will be brought to bear upon the portion exposed to the dynamical action of the water is thus calculated: Taking d to represent the depth of water in feet lineal, the pressure per foot lineal of the dam will be proportional to the weight of a right-angled triangle of water, whose sides = d ; or as a cubic foot of water weighs $62\frac{1}{2}$ lbs. nearly, the pressure will be $\frac{d^2}{2} \times 62\frac{1}{2}$; and calling the length of the dam, in feet, l , the total pressure will be $= l \times \frac{125d^2}{4}$.

According to the laws of hydrodynamics, the centre of pressure is of course situated at $\frac{1}{3}d$ from the bottom; and therefore, if only one stay be necessary, it should be placed at that point. If more than one stay be necessary, on account of the great height of the dam, the succeeding ones must be placed at the centres of pressure of the other portions; or in other words, if three stays be employed, they must respectively be fixed at points measuring $\frac{1}{3}$, $\frac{1}{3}$, and $\frac{1}{3}$ from the bottom of the dam. In ordinary cases the dam is, however, made of a rectangular section, and does not depend on struts; and when this form is adopted, the thickness, or width, may be calculated as follows. Calling w the mean weight of the dam per cubic foot, h its height in feet, and d the depth of water; then t , the thickness, should be, $t = \frac{\sqrt{125d^3}}{3hw}$; for the moment of resistance of the dam is $= \frac{ht^2w}{2}$, and that of the water is $= \frac{125d^3}{6}$. According to Mr. Neville (whose paper on this subject,

in the 'Civil Engineers' and Architects' Journal,' 1849, contains the best practical information on the subject yet printed), it is customary to take the weight of a cubic foot of a coffer-dam at 90 lbs., but to reduce it to 30 lbs. per foot, if the water should be able to get under its seat. If struts should be used, Mr. Neville states that the distance of their feet, called k , should be made equal to $\frac{125d^3}{6hwt} - \frac{t}{2}$, following,

however, the notation adopted above, and supposing t , the thickness of the rectangular portion of the dam, to be given. This is usually the case in practice; for the hydroscopic qualities of the clay, used to fill in the space between the timber casings of such dams, requires that they should be at least from 2 to 3 feet apart; generally speaking the distance between the outer and inner rows of piles is made 4 feet. In the execution of coffer-dams, the system usually adopted is to drive guide-piles to mark the general limits of the enclosure. Horizontal *whales*, as they are called, are then attached to the guide-piles, and they serve to keep in place the *close* or the *sheet* piling, which forms the exposed face of the dam; occasionally, when great perfection of execution is required, the close piling is made with vertical grooves, or, to use the workmen's phrase, it is grooved and tongued. The intermediate space between the inner and the outer rows of sheet piling is then filled in with impermeable clay puddle; and when all connection between the external and the internal waters is thus intercepted, the latter is pumped out, so as to allow the ordinary building operations to be carried on as though on the dry land.

Very good descriptions of coffer-dams actually executed, under difficult circumstances, are to be met with in Perronet's 'Nouvelle Architecture Hydraulique;' in Sganzin's 'Cours de Construction;' in Semple's 'Treatise on Building in Water;' and in Cressy's 'Treatise on Bridges and Vaults.'

COFFIN, the box or chest in which dead bodies are put into the ground; also a mould of paste for a pie: from the Latin *cophinus*, and that from the Greek *κόφινος*, which properly meant a wicker basket. Wyntown, in his 'Chronicle,' uses *cofyne* for a shrine or box, and in the 'Pericles' of Shakspeare—at least of his time—it is so used: "Bid Nestor bring . . . my casket and my jewels; and bid Nicander bring me the satin coffin." We have another instance of the use of the word coffin for an ordinary chest in the Wardrobe Accounts of Edward IV., 8vo. Lond., 1830, p. 125: "For closyng and fastenyng of divers cofyns of fyrr, wherein the kyng's books were conveyed and caried from the king's great wardrobe in London to Eltham, v^d." The kistvaen, or coffin composed of rough stones, set edgewise at the sides and ends,

and covered with one or more flat stones, was common among the Britons; they are found in caverns, &c. in various parts of the kingdom. Sir Christopher Wren found stone coffins of the Saxon times, at the rebuilding of St. Paul's: and Gough adds that, from the 9th century to the reign of Henry III., stone coffins were in general use, that is, for persons of the higher classes. The bodies of the common people, not only in the Norman but also in the English era, as we see in the illuminations of ancient missals, were only wrapped in cloth, and so put into the ground. In this manner, Matthew Paris informs us, the monks of St. Alban's were buried, till the time of Abbot Warin, who died in 1195. He ordered that they should be buried in stone coffins, as more decent. Matthew Paris, on this occasion ('Vit. Abb. S. Alb.,' p. 95), charges him with innovations on established customs, to please the multitude. Many stone coffins remain of the 11th, 12th, and 13th centuries with crosses, crosiers, mitres, and inscriptions carved on the lids. Strutt says, in the reigns of Henry V. and VI., stone coffins were made with necks, distinguishing the head and shoulders. Coffins both of lead and wood are of early use. The former occur in numerous instances through different centuries: and that the Saxons buried in coffins of wood, occasionally, we have the testimony of Bede. Ceadda was so buried ('Hist. Eccl.,' l. iv., c. 3), as was Etheldreda, wife of Egfrid, king of the East Angles. (Ibid., l. iv., c. 29.) Sebba, king of the East Saxons, was buried at St. Paul's in a coffin of gray marble. (Ibid., l. iv., c. 11.) The forms and ornaments of various ancient coffins, mostly of stone, may be seen in the plates of illuminations in Strutt's 'Manners and Customs,' vol. i., pl. xxxix., xlv., lvi., and in Gough's 'Sepulchral Monuments.'

COGNOVIT, or more technically *cognovit actionem*, is a formal acknowledgment or admission by one person, commonly a defendant, that another person, ordinarily the plaintiff in an action, has a good right of action or just claim against him. Thus it is not unusual for a defendant, when served with a writ for a claim to which he has no answer, to give a warrant of attorney as it is called; that is, in effect, to admit the plaintiff's claim, so that all expense is saved, and judgment at once entered up for the plaintiff. In almost all cases the defendant's failure to appear to a writ is, in effect, a *cognovit actionem*, as the plaintiff may, if the action be for the recovery of a specific amount, at once sign judgment for that amount. If the action be for damages, he may sign an interlocutory judgment by default after certain forms, and afterwards ascertain the amount for which he is entitled to final judgment by the verdict of a jury. The advantage of having a claim admitted beyond dispute has made it a common practice for a debtor to strengthen the security of his creditor by executing a warrant of attorney to an attorney named by the creditor, authorising him to confess a judgment in an action to be brought by the creditor against the debtor for the specific sum due to him. In order to prevent debtors being defrauded, such a warrant of attorney or *cognovit* is of no force unless there be present an attorney of one of the superior courts, on behalf of the party who gives it, expressly named by him, and attending at his request, to inform him of the effect of the instrument before he executes it, and who must subscribe as a witness to the execution, and declare himself to be the attorney for the party. In order to be effectual as against the assignees of the debtor, if he should become bankrupt or insolvent, warrants of attorney and *cognovits* must further be filed in the Court of Queen's Bench within twenty-one days after execution.

(1 & 2 Vict. c. 110. Chitty's *Practice*, by Prentice, tit. 'Cognovit' and 'Warrant of Attorney.')

COG-WHEEL. The tooth-wheels used in machinery for the transmission of motion are called *cog-wheels* when the teeth are made of wood; when the teeth are of iron such wheels are simply called *tooth-wheels*, and subsidiarily they are known as pinions, bevelled wheels, annular, or crown wheels, according to their sizes and their relative positions with respect to the rest of the machinery. [MACHINERY.] Both cogs and teeth, however, are the projections on one wheel fitting into the space left between the two teeth of the corresponding wheel, in such wise that one of those wheels cannot move without putting the other in motion. The thickness of cogs, or teeth, is measured on the pitch circle of the wheel; and the interval between one cog and the next to it is called the depth, and is made equal to the thickness, augmented by from $\frac{1}{10}$ to $\frac{1}{15}$ of that dimension, according to the perfection of the work. The breadth of a cog is its dimension upon the axis of rotation; the portion of its height (or of the clear united length from the top to the bottom of the cog) which lies beyond the pitch circle is called the face; and that which lies within that circle is called the flank. The pitch of wheels of this description is the distance measured from centre to centre of the cogs, or of the intermediate spaces.

Cog-wheels are usually made with cast-iron frames, in which rectangular holes are left to receive the wooden cogs or teeth, and these pass through the whole thickness of the rim, and are retained in their situations by means of keys or wedges. The cogs are thus wedged up before being cut into their definite form, and the latter must be set out with all the care usually observed in executing teeth-wheels. [TOOTH-WHEEL.] When well made, cog-wheels are preferable to ordinary teeth-wheels, especially in large work, on account of their working more smoothly and with less noise; but great precautions must be observed in the selection of the wood of which the cogs are made, and

they must be protected from the effects of humidity. Hornbeam, or box-wood, are the materials best fitted for this purpose. Cog-wheels should be greased, and a little black-lead may be mixed with the grease; but oil should not be applied to them. (See Camus, 'Treatise on the Teeth of Wheels,' translated by Hawkins, Lond. 1842; Buchanan's 'Essay on the Teeth of Wheels,' Lond. 1808, &c.)

COHESION. [ATTRACTION.]

COHESION, MAGNETIC. [MAGNETISM.]

COHORT was a division of the Roman legion. The term (cohors, or chors, the Greek *χοῖρος*) originally signified an enclosure for sheep or poultry, and was afterwards used to designate the number of men which could stand within such an enclosure. The Roman legion, as well as the citizens at the census [CENSUS], was subdivided into centuries. A century did not always consist of a hundred; the number varied. A legion consisted of ten cohorts; each cohort contained three maniples, and each maniple two centuries; hence there were thirty maniples and sixty centuries, and in the whole legion there must have

been sixty centurions. The different centurions received names indicative of their rank. Of the two centurions in a maniple, one ranked before the other, and had the title prior; the second was called posterior. The first centurion of the first maniple had the charge of the eagle, the great standard of the legion; he was ranked with the equites. He was called *centurio primi pili* (Livius, xxv., 19), or simply *primus centurio*, or *primus pilus* (Cæsar, 'De Bell. Gall.' ii. 25). The office was lucrative, but it was not always the reward of merit; favour or money in some cases procured it (Cicero, 'Pis.' 36); under the emperors it was bestowed generally from caprice (Vegetius, xi. 3, in Pitiscus, 'Lexic. Antiq. Rom.'). The badge of a centurion was a vine rod, which the soldiers sometimes felt (Tacitus, 'Ann.' i. 23).

The *cohortes alares*, or *alarie* (Liv. x. 40, 43), were the troops of the auxiliaries and the allies which were stationed in the wings (*alæ*).

The *cohors prætoria* was a select band which usually attended the prætor (Sallustius, 'Catil.' c. 60; Pitiscus, 'Lexicon Antiquit. Rom., in Cohors, Centurio.')

END OF VOLUME II.

The first of these is the fact that the church is a body of men and women, and as such it is subject to the same laws of growth and decay as any other human institution. It is not a static entity, but a living organism, and its life is determined by the quality of its members and the way in which they relate to one another. The church is not a mere collection of individuals, but a community, and its strength lies in the unity and fellowship of its members. It is this unity and fellowship which enable the church to withstand the pressures of the world and the devil, and to remain a light in a dark world.

The second of these is the fact that the church is a body of men and women, and as such it is subject to the same laws of growth and decay as any other human institution. It is not a static entity, but a living organism, and its life is determined by the quality of its members and the way in which they relate to one another. The church is not a mere collection of individuals, but a community, and its strength lies in the unity and fellowship of its members. It is this unity and fellowship which enable the church to withstand the pressures of the world and the devil, and to remain a light in a dark world.
